Executive Summary

Linked data is a process for embedding the descriptive information of archives into the very fabric of the Web. By transforming archival description into linked data, an archivist will enable other people as well as computers to read and use their archival description, even if the others are not a part of the archival community. The process goes both ways. Linked data also empowers archivists to use and incorporate the information of other linked data providers into their local description. This enables archivists to make their descriptions more thorough, more complete, and more value-added. For example, archival collections could be automatically supplemented with geographic coordinates in order to make maps, images of people or additional biographic descriptions to make collections come alive, or bibliographies for further reading.

Publishing and using linked data does not represent a change in the definition of archival description, but it does represent an evolution of how archival description is accomplished. For example, linked data is not about generating a document such as EAD file. Instead it is about asserting sets of statements about an archival thing, and then allowing those statements to be brought together in any number of ways for any number of purposes. A finding aid is one such purpose. Indexing is another purpose. For use by a digital humanist is another purpose. While EAD files are encoded as XML documents and therefore very computer readable, the reader must know the structure of EAD in order to make the most out of the data. EAD is archives-centric. The way data is manifested in linked data is domain-agnostic.

The objectives of archives include collection, organization, preservation, description, and often times access to unique materials. Linked data is about description and access. By taking advantages of linked data principles, archives will be able to improve their descriptions and increase access. This will require a shift in the way things get done but not what gets done. The goal remains the same.

Many tools are ready exist for transforming data in existing formats into linked data. This data can reside in Excel spreadsheets, database applications, MARC records, or EAD files. There are tiers of linked data publishing so one does not have to do everything all at once. But to transform existing information or to maintain information over the long haul requires the skills of many people: archivists & content...
specialists, administrators & managers, metadata specialists & catalogers, computer programers & systems administrators.

Moving forward with linked data is a lot like touring to Rome. There are many ways to get there, and there are many things to do once you arrive, but the result will undoubtably improve your ability to participate in the discussion of the human condition on a world wide scale.
Acknowledgements

The creation of this guidebook is really the effort of many people, not a single author. First and foremost, thanks goes to Anne Sauer and Eliot Wilczek. Anne saw the need, spearheaded the project, and made it a reality. Working side-by-side was Eliot who saw the guidebook to fruition. Then there is the team of people from the Working Group: Greg Colati, Karen Gracy, Corey Harper, Michelle Light, Susan Pyzynski, Aaron Rubinstein, Ed Summers, Kenneth Thibodeau, and Kathy Wisser. These people made themselves available for discussion and clarification. They provided balance between human archival practice and seemingly cold computer technology. Additional people offered their advice into the issues of linked data in archives including: Kevin Cawley, Diane Hillman, Mark Matienzo, Ross Singer, and Jane & Ade Stevenson. They filled in many gaps. Special thanks goes to my boss Tracey Bergstrom who more than graciously enabled some of this work to happen on company time. The questions raised by the anonymized library school student are definitely appreciated. The Code4Lib community was very helpful -- a sort of reality check. And then there are the countless other people who listened over and over again about what linked data is, is not, and what it can do. A big "thank you" goes to all.
Introduction

"Let's go to Rome!"

The purpose of this guidebook is to describe in detail what linked data is, why it is important, how you can publish it to the Web, how you can take advantage of your linked data, and how you can exploit the linked data of others. For the archivist, linked data is about universally making accessible and repurposing sets of facts about you and your collections. As you publish these fact you will be able to maintain a more flexible Web presence as well as a Web presence that is richer, more complete, and better integrated with complementary collections. The principles behind linked data are inextricably bound to the inner workings of the Web. It is standard of practice that will last as long as the Web lasts, and that will be long into the foreseeable future. The process of publishing linked data in no way changes the what of archival practice, but it does shift how archival practice is accomplished. Linked data enables you to tell the stories of your collections, and it does in a way enabling you to reach much wider and more global audiences.

Linked Archival Metadata: A Guidebook provides archivists with an overview of the current linked data landscape, defines basic concepts, identifies practical strategies for adoption, and emphasizes the tangible payoffs for archives implementing linked data. It focuses on clarifying why archives and archival users can benefit from linked data and will identify a graduated approach to applying linked data methods to archival description.

"Let's go to Rome!" This book uses the metaphor of a guidebook, specifically a guidebook describing a trip to Rome. Any trip abroad requires an understanding of the place where you intend to go, some planning, some budgeting, and some room for adventure. You will need to know how you are going to get there, where you are going to stay, what you are going to eat, what you want to see and do once you arrive, and what you might want to bring back as souvenirs. You behooves you to know a bit of the history, customs, and language. This is also true of your adventure to Linked Data Land. To that end, this guidebook is divided into the following sections:
• What is linked data and why should I care? - A description of the beauty of Rome and why you should want to go there

• Linked data: A Primer - A history of Rome, an outline of its culture, its language, its food, its customs, and what it is all about today

• Strategies - Sets of things you ought to be aware of and plan for before embarking on your adventure, and then itineraries for immersing yourself and enjoying everything the Eternal City has to offer once you have arrived

• Details - Lists of where to eat, what to do depending on your particular interests, and how to get around the city in case you need help

The Guidebook is a product of the Linked Archival Metadata planning project (LiAM), led by the Digital Collections and Archives at Tufts University and funded by the Institute of Museum and Library Services (IMLS). LiAM’s goals include defining use cases for linked data in archives and providing a roadmap to describe options for archivists intending to share their description using linked data techniques.
What is linked data, and why should I care?

"Tell me about Rome. Why should I go there?"

Linked data is a standardized process for sharing and using information on the World Wide Web. Since the process of linked data is woven into the very fabric of the way the Web operates, it is standardized and will be applicable as long as the Web is applicable. The process of linked data is domain agnostic meaning its scope is equally apropos to archives, businesses, governments, etc. Everybody can and everybody is equally invited to participate. Linked data is application independent. As long as your computer is on the Internet and knows about the World Wide Web, then it can take advantage of linked data.

Linked data is about sharing and using information (not mere data but data put into context). This information takes the form of simple "sentences" which are intended to be literally linked together to communicate knowledge. The form of linked data is similar to the forms of human language, and like human languages, linked data is expressive, nuanced, dynamic, and exact all at once. Because of its atomistic nature, linked data simultaneously simplifies and transcends previous information containers. It reduces the need for profession-specific data structures, but at the same time it does not negate their utility. This makes it easy for you to give your information away, and for you to use other people's information.

The benefits of linked data boil down to two things: 1) it makes information more accessible to both people as well as computers, and 2) it opens the doors to the creation any number of knowledge services limited only by the power of human imagination. Because it standardized, agnostic, independent, and mimics human expression linked data is more universal than many of the current processes of information dissemination. Universality infers decentralization, and decentralization promotes dissemination. On the Internet anybody can say anything at anytime. In the aggregate, this is a good thing and it enables information to be combined in ways yet to be imagined. Publishing information as linked data enables you to seamlessly enhance your own knowledge services as well as simultaneously enhance the knowledge of others.
"Rome is the Eternal City. After visiting Rome you will be better equipped to participate in the global conversation of the human condition."
"Okay. My interest is piqued. Please tell me more about Rome's history, culture, and geography. What are the people like, what do they do for a living, and how can I get around if I'm going to stay for a while?"

This section describes linked data in much greater detail. Specifically, this section introduces the reader to the history of linked data, a data model called RDF, RDF "serializations", RDF publishing models, ways RDF has been used, SPARQL,...

History

"Rome rose, fell, and has risen again."

The history of linked data begins with a canonical Scientific American article, "The Semantic Web" by Tim Berners-Lee, James Hendler, and Ora Lassila in 2001. The article described an environment where Internet-wide information was freely available for both people and computers with the ultimate purpose of bringing new knowledge to light. To do this people were expected to: 1) employ a data model called RDF for organizing their information, and 2) express the RDF as XML files on the Web. In a time when the predominate mode of data modeling was rooted in relational databases, the idea of RDF was difficult for many people to understand. Of the people who did understand, many of them thought expressing RDF as XML made things too difficult to read. Despite these limitations, there was a flurry of academic research done against the idea of the Semantic Web, but the term "linked data" had yet to be coined.

Around this same time REST-ful computing was being articulated by the Internet community. Simply put, REST-ful computing is a way for computers to request and share information over the World Wide Web. All one usually had to do is submit a very long URL (complete with numerous name/value pairs) to a Web server, and the Web server was then expected to return computer readable data. Many computer programmers and people who could write HTML picked up on the idea.

1 canonical article - http://csis.pace.edu/~marchese/CS835/Lec9/112_SemWeb.pdf

--------------------------
13 of 121
quickly. REST-ful computing was seen as immediately practical with little need to learn anything about "data models". Because the ideas behind the Semantic Web may have been oversold and because REST-ful computing was seen as so easy to implement, REST-ful computing flourished (and continues to flourish) while interest in the Semantic Web waned.

Then, in 2006, Tim Berners-Lee concretely described how to make the Semantic Web a reality. In it he listed a four-step process for making linked data freely available on the Web. It is a practical process many people can identify with. The description also advocated for simpler URLs (URLs sans long name/value pairs) for identifying anything in the world -- people, places, or things both real and imaginary. At this same time new ways of expressing RDF were articulated and becoming popular. RDF manifested as XML was no longer the only choice. Also at this same time a few entrepreneurial individuals were beginning to provide software applications and services for creating, maintaining, and distributing RDF. This made the work of some people easier. An increasing number of specialized communities -- governments, scientific communities, professional associations, and "cultural heritage institutions" -- began making their data and metadata freely available on the Web, accessible via REST-ful computing or RDF. These developments, plus a kinship of "all things open" (open source software, open access publishing, open data, etc.) to the ideals of the Semantic Web, probably contributed to the current interest in the newly coined phrase "linked data". Progress and developments in linked data (now rarely called the Semantic Web) continue but at a more measured pace. Linked data communities are strengthening. The ideas behind modeling data as RDF are becoming better understood. Production-level RDF services are being implemented. While the ideas behind RDF, linked data, and ultimately the Semantic Web have yet to become mainstream, interest is now in waxing phase.

What is RDF?

"Rome is inextricably linked to its Roman heritage."

__________

2 design issues - http://www.w3.org/DesignIssues/LinkedData.html
Linked Data is a process for sharing human knowledge on the World Wide Web. It is about asserting relationships between things and then linking these things together to express knowledge. These two things (asserting relationships and linking) are at the very heart of linked data, and they are the defining characteristics of RDF. This section describes RDF in greater detail.

RDF is an acronym for Resource Description Framework. As the name implies, it is a structure (framework) for asserting relationships (descriptions) between things (resources). It is a model for organizing data. Unlike the data model of spreadsheets made up of rows & columns, or the data model of joined tables as in relational databases, the data model of RDF is based on the idea of a triple -- a simple "sentence" with three distinct parts: 1) a subject, 2) a predicate, and 3) an object. The subject of each triple is expected to be a URI (for the time being, think "URL"), and this URI is expected to point to things either real or imaginary. Similarly, the object of each triple is a URI, but it can also be a literal -- meaning a word, phrase, narrative, or number. Predicates take the form of URIs too, and they are intended to denote relationships between the subjects and objects. To extend the analogy of the sentence further, think of subjects and objects as if they were nouns, and think of predicates as if they were verbs.

RDF statements are often illustrated as arced graphs where subjects and objects are nodes in the illustration and predicates are lines connecting the nodes:

[ subject ] --- predicate ---> [ object ]

The "linking" in linked data happens when sets of RDF statements share common URIs. By doing so, the subjects of RDF statements end up having many characteristics, and the objects of URIs point to other subjects in other RDF statements. This linking process transforms independent sets of RDF statements into a web of interconnections, and this is where the Semantic Web gets its name:

/ --- a predicate --------> [ an object ]
[ subject ] - |  --- another predicate ---> [ another object ]
\ --- a third predicate ---> [ a third object ]

|  
|  |
yet another predicate

--------------------------
15 of 121
An example is in order. Suppose there is a thing called Rome, and it will be represented with the following URI: http://example.org/rome. We can now begin to describe Rome using triples:

```
<table>
<thead>
<tr>
<th>subjects</th>
<th>predicates</th>
<th>objects</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://example.org/rome">http://example.org/rome</a></td>
<td>has name</td>
<td>&quot;Rome&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/rome">http://example.org/rome</a></td>
<td>has founding date</td>
<td>&quot;1000 BC&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/rome">http://example.org/rome</a></td>
<td>has description</td>
<td>&quot;A long long time ago,...&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/rome">http://example.org/rome</a></td>
<td>is a type of</td>
<td><a href="http://example.org/city">http://example.org/city</a></td>
</tr>
<tr>
<td><a href="http://example.org/rome">http://example.org/rome</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/italy">http://example.org/italy</a></td>
</tr>
</tbody>
</table>
```

The corresponding arced graph would look like this:

```
/ --- has name ------------> [ "Rome" ]
|  --- has description -----> [ "A long time ago,..." ]
[ http://example.org/rome ] - |  --- has founding date ---> [ "1000 BC" ]
|  --- is a sub-part of  ---> [ http://example.org/italy ]
\ --- is a type of --------> [ http://example.org/city ]
```

In turn, the URI http://example.org/italy might have a number of relationships asserted against it also:

```
<table>
<thead>
<tr>
<th>subjects</th>
<th>predicates</th>
<th>objects</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://example.org/italy">http://example.org/italy</a></td>
<td>has name</td>
<td>&quot;Italy&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/italy">http://example.org/italy</a></td>
<td>has founding date</td>
<td>&quot;1923 AD&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/italy">http://example.org/italy</a></td>
<td>is a type of</td>
<td><a href="http://example.org/country">http://example.org/country</a></td>
</tr>
<tr>
<td><a href="http://example.org/italy">http://example.org/italy</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/europe">http://example.org/europe</a></td>
</tr>
</tbody>
</table>
```

Now suppose there were things called Paris, London, and New York. They can be represented in RDF as well:

```
<table>
<thead>
<tr>
<th>subjects</th>
<th>predicates</th>
<th>objects</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://example.org/paris">http://example.org/paris</a></td>
<td>has name</td>
<td>&quot;Paris&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/paris">http://example.org/paris</a></td>
<td>has founding date</td>
<td>&quot;100 BC&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/paris">http://example.org/paris</a></td>
<td>has description</td>
<td>&quot;You see, there's this tower...&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/paris">http://example.org/paris</a></td>
<td>is a type of</td>
<td><a href="http://example.org/city">http://example.org/city</a></td>
</tr>
<tr>
<td><a href="http://example.org/paris">http://example.org/paris</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/france">http://example.org/france</a></td>
</tr>
<tr>
<td><a href="http://example.org/london">http://example.org/london</a></td>
<td>has name</td>
<td>&quot;London&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/london">http://example.org/london</a></td>
<td>has description</td>
<td>&quot;They drink warm beer here.&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/london">http://example.org/london</a></td>
<td>has founding date</td>
<td>&quot;100 BC&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/london">http://example.org/london</a></td>
<td>is a type of</td>
<td><a href="http://example.org/city">http://example.org/city</a></td>
</tr>
<tr>
<td><a href="http://example.org/london">http://example.org/london</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/england">http://example.org/england</a></td>
</tr>
<tr>
<td><a href="http://example.org/newyork">http://example.org/newyork</a></td>
<td>has founding date</td>
<td>&quot;1640 AD&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/newyork">http://example.org/newyork</a></td>
<td>has name</td>
<td>&quot;New York&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/newyork">http://example.org/newyork</a></td>
<td>has description</td>
<td>&quot;It is a place that never sleeps.&quot;</td>
</tr>
</tbody>
</table>
```
Furthermore, each of "countries" can be have relationships denoted against them:

<table>
<thead>
<tr>
<th>subjects</th>
<th>predicates</th>
<th>objects</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://example.org/unitedstates">http://example.org/unitedstates</a></td>
<td>has name</td>
<td>&quot;United States&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/unitedstates">http://example.org/unitedstates</a></td>
<td>has founding date</td>
<td>&quot;1776 AD&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/unitedstates">http://example.org/unitedstates</a></td>
<td>is a type of</td>
<td><a href="http://example.org/country">http://example.org/country</a></td>
</tr>
<tr>
<td><a href="http://example.org/unitedstates">http://example.org/unitedstates</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/northamerica">http://example.org/northamerica</a></td>
</tr>
<tr>
<td><a href="http://example.org/england">http://example.org/england</a></td>
<td>has name</td>
<td>&quot;England&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/england">http://example.org/england</a></td>
<td>has founding date</td>
<td>&quot;1066 AD&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/england">http://example.org/england</a></td>
<td>is a type of</td>
<td><a href="http://example.org/country">http://example.org/country</a></td>
</tr>
<tr>
<td><a href="http://example.org/england">http://example.org/england</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/europe">http://example.org/europe</a></td>
</tr>
<tr>
<td><a href="http://example.org/france">http://example.org/france</a></td>
<td>has name</td>
<td>&quot;France&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/france">http://example.org/france</a></td>
<td>has founding date</td>
<td>&quot;900 AD&quot;</td>
</tr>
<tr>
<td><a href="http://example.org/france">http://example.org/france</a></td>
<td>is a type of</td>
<td><a href="http://example.org/country">http://example.org/country</a></td>
</tr>
<tr>
<td><a href="http://example.org/france">http://example.org/france</a></td>
<td>is a sub-part of</td>
<td><a href="http://example.org/europe">http://example.org/europe</a></td>
</tr>
</tbody>
</table>

The resulting arced graph of all these triples might look like this:

[INERT ARCED GRAPH HERE.]

From this graph, new information can be inferred as long as one is able to trace connections from one node to another node through one or more arcs. For example, using the arced graph above, questions such as the following can be asked and answered:

- What things are denoted as types of cities, and what are their names?
- What is the oldest city?
- What cities were founded after the year 1 AD?
- What countries are sub-parts of Europe?
- How would you describe Rome?

In summary, RDF is data model -- a method for organizing discrete facts into a coherent information system. The model is built on the idea of triples whose parts are URIs or literals. Through the liberal reuse of URIs in and between sets of triples, questions surrounding the information can be answered and new information can be inferred.
RDF is the what of linked data. Everything else (ontologies & vocabularies, URIs, RDF "serializations" like RDF/XML, triple stores, SPARQL, etc.) are the how's. None of them will make any sense unless the reader understands that RDF is about establishing relationships between data for the purposes of sharing information.

Ontologies & vocabularies

"What languages do they speak in Rome?"

If RDF is built on "sentences" called triples, then by analogy ontologies & vocabularies are the "languages" of RDF. This section describes the role of ontologies & vocabularies in linked data.

Linked data is about putting data in the form of RDF on the Web. RDF is a data model for describing things (resources), and it made up of three parts: 1) subjects, 2) predicates, and 3) objects. The things being described are the subjects of RDF triples. They represent the things you own. The combined use of predicates and objects form the descriptions of the resources. These descriptions are akin to a language, or in the parlance of RDF, they are ontologies & vocabularies. While it is perfectly fine to create your own language to describe your own things, it behooves you to use one or more ontologies & vocabularies of others. Otherwise your descriptions will exist in a virtual silo with no interaction with outside resources. When outside ontologies & vocabularies are not employed in RDF, then the purpose of the linking in linked data gets defeated.

RDF ontologies & vocabularies are comprised of classes of objects and properties of those objects. The classes of objects posit the existence of things. They might posit the class of all people, places, events, etc. Properties are characteristics of the classes. People might have names and birth dates. Places have geographic coordinates. Events have dates, times, and descriptions.

There are quite a number of existing ontologies & vocabularies. Some of them of interest to readers of this guide are listed in another section, but a few are briefly discussed here. The first is FOAF (Friend Of A Friend). This ontology/vocabulary is used to describe

3 FOAF - [http://www.foaf-project.org](http://www.foaf-project.org)
people. It defines a number of classes, including but not limited to: agent, person, and document. Agents have properties such as mboxes (email addresses), various identifiers, topics of interest, etc. A person, which is a subclass of Agents inherits all of the properties of an agent, but also has a few of its own such as family names, various types of home pages, and images. Documents have properties such as topics and primary interests. If the resources you were describing were people (or agents), then it might want to draw on the FOAF ontology/vocabulary. If the entity named Rome had an email address, then its RDF arced graph might look like this:

[ http://example.org/rome ] --- has mbox ---> [ mailto:info@rome.it ]

Another ontology/vocabulary is DCMI Metadata Terms ("Dublin Core"). It posits the existence of things like: agent, rights statement, standard, and physical resource. It includes properties such as creator, title, description, various types of dates, etc. While the "Dublin Core" standard was originally used to describe bibliographic materials, it has matured and been widely adopted by a growing number of ontologists.

In a project called Linking Lives at the Archives Hub, an ontology/vocabulary for archival description was created. This ontology includes a few classes from FOAF (document, agent, etc.) but also has classes such as repository, archival resource, biographical history, and finding aid. Properties include various dates, extent, title, or has biographical history.

A final example is VIAF (Virtual International Authority File). This "ontology" is more akin to a "controlled vocabulary", and it is a list of people's names and URIs associated with them. VIAF is intended to be used in conjunction with things like DCMI's creator property. For example, if Romulus, one of the mythical twins and founders of Rome were associated with the entity of Rome, then the resulting arced graph might look like this:

[ http://example.org/rome ] --- has mbox ---> [ mailto:info@rome.it ]

4 DCMI Metadata Terms - http://dublincore.org/documents/dcmi-terms/
5 Linking Lives project - http://archiveshub.ac.uk/linkinglives/
6 Linking Lives ontology - http://data.archiveshub.ac.uk/def/
7 VIAF - http://viaf.org

-------------------
19 of 121
There are other controlled vocabularies of interest to the readers of
this book, including additional name authority files, subject
headings, language codes, country listings, etc. These and other
ontologies & vocabularies are listed later in the guidebook.

RDF and linked data is about making relationships between things.
These relationships are denoted in the predicates of RDF triples, and
the types of relationships are defined in ontologies & vocabularies.
These ontologies & vocabularies are sometimes called schema. In the
world of bibliography (think "Dublin Core"), these relationship types
include things such "has title", "has subject", or "has author". In
other ontologies, such as Friend of a Friend (FOAF), there are
relationship types such as "has home page", "has email address", or
"has name". Obviously there are similarities between things like "has
author" and "has name", and consequently there are other ontologies
(schemas) allowing equivocation, similarity, or hierarchy to be
denoted, specifically RDFS, SKOS, and OWL.

In the world of archives, collections and their items are described.
Think metadata. Some of this metadata comes from name authority lists
and controlled vocabulary terms. Many of the authority lists and
controlled vocabulary terms used by archives exist as linked data.
Thus, when implementing RDF in archives it is expected to state things
such as "This particular item was authored by this particular URI", or
"This particular collection has a subject of this particular URI"
where the URIs are values pointing to items in named authority lists
or controlled vocabularies.

Probably one of the more difficult intellectual tasks you will have
when it comes to making your data and information available as linked
data will be the selection of one or more ontologies used to make your
RDF. Probably the easiest -- but not the most precise -- way to think
about ontologies is as if they were fields in a MARC record or an EAD
file. Such an analogy is useful, but not 100% correct. Probably the
best way to think of the ontologies is as if they were verbs in a
sentence denoting relationships between things – subjects and objects.

But if ontologies are sets of "verbs", then they are akin to human
language, and human language is ambiguous. Therein lies the difficulty
with ontologies. There is no "right" way to implement them. Instead, there is only best or common practice. There are no hard and fast rules. Everything comes with a bit of interpretation. The application and use of ontologies is very much like the application and use of written language in general. In order for written language to work well two equally important things need to happen. First, the writer needs to be able to write. They need to be able to choose the most appropriate language for their intended audience. Shakespeare is not "right" with his descriptions of love, but instead his descriptions of love (and many other human emotions) resonate with a very large number of people. Second, written language requires the reader to have a particular adeptness as well. Shakespeare can not be expected to write one thing and communicate to everybody. The reader needs to understand English, or the translation from English into another language needs to be compete and accurate.

The Internet, by design, is a decentralized environment. There are very few rules on how it is expected to be used. To a great extent it relies on sets of behavior that are more common practice as opposed to articulated rules. For example, what "rules" exist for tweets on Twitter? What rules exist for Facebook or blog postings. Creating sets of rules will not fly on the Internet because there is no over-arching governing body to enforce any rules. Sure, there are things like Dublin Core with their definitions, but those definitions are left to interpretation, and there are no judges nor courts nor laws determining whether or not any particular application of Dublin Core is "correct". Only the common use of Dublin Core is correct, and its use is not set in stone. There are no "should's" on the Internet. There is only common practice.

With this in mind, it is best for you to work with others both inside and outside your discipline to select one or more ontologies to be used in your linked data. Do not think about this too long nor too hard. It is a never-ending process that is never correct. It is only a process that approximates the best solution.

"The people of Rome speak Italian, mostly. But it is not difficult to hear other languages as well. Rome is an international city."

RDF serializations

-----------------------------------------------

"While Romans speak Italian, mostly. There are different dialects, each with its own distinct characteristics."

RDF is a data model, and so far it has only been described (and illustrated) in the abstract. RDF needs to be exchanged between computers, and therefore it needs to be more concretely expressed. There are a number of ways RDF can be expressed, and these expressions are called "serializations".

RDF (Resource Description Framework) is a conceptual data model made up of "sentences" called triples — subjects, predicates, and objects. Subjects are expected to be URIs. Objects are expected to be URIs or string literals (think words, phrases, or numbers). Predicates are "verbs" establishing relationships between the subjects and the objects. Each triple is intended to denote a specific fact.

When the idea of the Semantic Web was first articulated XML was the predominant data structure of the time. It was seen as a way to encapsulate data that was both readable by humans as well as computers. Like any data structure, XML has both its advantages as well as disadvantages. On one hand it is easy to determine whether or not XML files are well-formed, meaning they are syntactically correct. Given a DTD, or better yet, an XML schema, it is also easy to determine whether or not an XML file is valid — meaning does it contain the necessary XML elements, attributes, and are they arranged and used in the agreed upon manner. XML also lends itself to transformations into other plain text documents through the generic, platform-independent, XSLT (Extensible Stylesheet Language Transformation) process. Consequently, RDF was originally manifested — made real and "serialized" — though the use of RDF/XML.

The example of RDF at the beginning of the Guidebook was an RDF/XML serialization:

```xml
<?xml version="1.0"?>
    <dcterms:creator>
      <foaf:Person rdf:about="http://id.loc.gov/authorities/names/n79089957">
        <foaf:gender>male</foaf:gender>
      </foaf:Person>
    </dcterms:creator>
  </rdf:Description>
</rdf:RDF>
```
On the other hand, XML, almost by definition, is verbose. Element names are expected to be human-readable and meaningful, not obtuse nor opaque. The judicious use of special characters (&, <, >, " , and ") as well as entities only adds to the difficulty of actually reading XML. Consequently, almost from the very beginning people thought RDF/XML was not the best way to express RDF, and since then a number of other syntaxes – serializations – have manifested themselves.

Below is the same RDF serialized in a format called Notation 3 (N3), which is very human readable, but not extraordinarily structured enough for computer processing. It incorporates the use of a line-based data structure called N-Triples used to denote the triples themselves:

```xml
@prefix foaf: <http://xmlns.com/foaf/0.1/>.
@prefix rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>.
@prefix dcterms: <http://purl.org/dc/terms/>.
<http://id.loc.gov/authorities/names/n79089957> a foaf:Person;
 foaf:gender "male".
```

JSON (JavaScript Object Notation) is a popular data structure inherent to the use of JavaScript and Web browsers, and RDF can be expressed in a JSON format as well:

```json
{
  "http://purl.org/dc/terms/creator": [
   {
    "type": "uri",
    "value": "http://id.loc.gov/authorities/names/n79089957"
   }
  ],
  "http://id.loc.gov/authorities/names/n79089957": {
   "http://xmlns.com/foaf/0.1/gender": [
    {
     "type": "literal",
     "value": "male"
    }
   ],
   "http://www.w3.org/1999/02/22-rdf-syntax-ns#type": [
    {
     "type": "uri",
     "value": "http://xmlns.com/foaf/0.1/Person"
    }
   ]
  }
}
```
Just about the newest RDF serialization is an embellishment of JSON called JSON-LD. Compare & contrasts the serialization below to the one above:

```json
{
  "@graph": [
    {
      "http://purl.org/dc/terms/creator": {
        "@id": "http://id.loc.gov/authorities/names/n79089957"
      }
    },
    {
      "@id": "http://id.loc.gov/authorities/names/n79089957",
      "@type": "http://xmlns.com/foaf/0.1/Person",
      "http://xmlns.com/foaf/0.1/gender": "male"
    }
  ]
}
```

RDFa represents a way of expressing RDF embedded in HTML, and here is such an expression:

```html
<div xmlns="http://www.w3.org/1999/xhtml"
     prefix="
         foaf: http://xmlns.com/foaf/0.1/
         rdf: http://www.w3.org/1999/02/22-rdf-syntax-ns#
         dcterms: http://purl.org/dc/terms/
         rdfs: http://www.w3.org/2000/01/rdf-schema#"
>
    <div rel="dcterms:creator">
      <div typeof="foaf:Person" about="http://id.loc.gov/authorities/names/n79089957">
        <div property="foaf:gender" content="male"/>
      </div>
    </div>
  </div>
</div>
```

The purpose of publishing linked data is to make RDF triples easily accessible. This does not necessarily mean the transformation of EAD or MARC into RDF/XML, but rather making accessible the statements of RDF within the context of the reader. In this case, the reader may be a human or some sort of computer program. Each serialization has its own strengths and weaknesses. Ideally an archive will have figure out ways exploit each of the RDF serializations for specific publishing purposes.
For a good time, play with the RDF Translator which will convert one RDF serialization into another.\textsuperscript{8}

The RDF serialization process also highlights how data structures are moving away from a document-centric models to a statement-central models. This too has consequences for way cultural heritage institutions, like archives, think about exposing their metadata, but that is the topic of another essay.

Publishing linked data

"Rome is a place of many neighborhoods, each with its own flavor, but in each of the neighborhoods you will experience an essence of what it means to be Roman."

Just as there are many ontologies & vocabularies, just as there are many ways to express RDF, there are many ways to publish RDF. This section introduces many of them, and they are discussed in greater detail later in the book.

Once your data has been modeled as RDF, it will be time to make it accessible on the Web. There are many ways to do this, and each of the rely on how your data/information is locally stored. Your data/information is probably already modeled in some sort of store, and it will be the job of somebody to transform that data into RDF. For example, the store might be a simple spreadsheet -- a flat file or rows & columns of information. In this model, each row in the spreadsheet will need to have a URI "minted" for it. That URI will then have predicates denoting the names of each column. Finally, the object of each RDF triple will be the value of each item in the row. The result will be set of RDF in the form of some serialization. This can be put on the Web directly, or saved in a triple store, described below.

If the data/information is modeled in a relational database, then the process of manifesting it as RDF is very similar to the process of transforming a flat file for rows & columns. There are two other options as well. One is the use of R2RML, a relational database to RDF

\textsuperscript{8} RDF Translator - \url{http://rdf-translator.appspot.com}
modeling language. Another option is to use a piece of open source software called D2RQ which will convert a well-designed relational database into RDF. In either case, the resulting RDF could be saved as one or more files on a Web server or shared dynamically directly from the database.

Many people use some sort of document to model their data/information. In the world of archives, this document may be an EAD file or a set of MARC records. While not ideal, it is possible to use XSL to transform the EAD or MARC into a RDF serializations. This is the process employed by the Guidebook's "sandbox" application. This is the same process used by a number of more formal projects including Linking Lives and ReLoad.

If RDF serializations are saved as files on the Web, as in the examples outlined above, then those files may be simple dumps of data which are large files consisting of huge numbers of triples. The URLs of those files are then listed in some sort of Web page intended for people to read. Sometimes the locations of these RDF files are listed in a different type of file called a VOID file.

Alternatively, RDF might be published side-by-side their human readable HTML counter-parts. The VIAF URIs are good examples. If this method is employed, then a process called "content negotiation" is expected to be implemented. Content negotiation is an integral part of the way the World Wide Web operates. It is method for one computer to request a specific form of data/information from a server. In terms of linked data, a computer can request the content of a URI in the form of HTML or RDF, and the remote server will provide the information in the desired format, if available. Content negotiation is described in greater detail later in the Guidebook.

Some people's data/information may be modeled in a content management system, like Drupal. These systems generate HTML on-the-fly. In these

---

9 R2RML - http://www.w3.org/TR/r2rml/
10 D2RQ - http://d2rq.org/
12 VOID - http://www.w3.org/TR/void/
cases it is a good idea embed RDF into the HTML using RDFa.\textsuperscript{13} RDFa is also an option when generating HTML out of databases on-the-fly.

Finally, there exist "databases" specifically designed to store RDF triples. These "databases" are called "triple stores". Along side these triple stores are methods for searching their contents. This searching mechanism is called SPARQL, and SPARQL "endpoints" may be available on the Web. A number of triple stores are listed later in the Guidebook, and a SPARQL tutorial is available as well.

In summary, there are many ways of publishing linked data. At first glance, it may seem as if there are too many choice and difficult to implement, but in reality modeling your data as RDF is much more challenging.

"Rome has many places to eat. Food is available in cafes, open air markets, family owned grocery stores, and commercial conglomerates. There are many ways to get food to the consumer."

Linked open data

"Rome has long understood the benefits of common areas, hence freely accessible squares, fountains, and market places."

Some people make a distinction between linked data and linked open data (LOD). Linked data is what has been described so far in this guidebook. It is a process for making data and metadata available on the Web using RDF as the underlying data model and incorporating into it as many links (URIs) as possible. This process does not necessarily stipulate any intellectual property claims on the published data and metadata, but linked data only works if it is made available with all copyright waived. This is often called the Creative Commons Zero (CC0) license. (Intellectual property claims can be explicitly stated through the use of VOID files -- sets of triples using the VOID ontology and published along side RDF files.) For the most part data and metadata accessible via linked data is assumed to free, as in gratis and without financial obligation. At the same time, consumers

\textsuperscript{13} RDFa - \url{http://www.w3.org/TR/xhtml-rdfa-primer/}

-----------------------------
27 of 121
of linked data are expected to acknowledge the time and effort others have spent in the creation of the consumed data, and consumers are not expected to call the data their own. This is an unspoken courtesy.

LOD is linked data that is explicitly denoted as free, as in gratis and without financial obligation. The idea seems to have been born from the idea of all things open (open source software and open access publishing). There is a strong community of LOD advocates in libraries, archives, and museums. The community is called LODLAM and has sponsored a few summits.\textsuperscript{14} The Open Knowledge Foundation is also a very strong advocate for LOD.\textsuperscript{15}

Strictly speaking linked data is a process, and linked open data is a thing. For all intents and purposes, this guidebook assumes the data and information made accessible via linked data is linked open data, but there might come a time in the future when access controls are places against some linked data. The data and information of linked data is not necessarily provided gratis.

Consuming linked data

"Rome, like any other city, is full of give and take."

Publishing linked data is only half of the equation. Consuming linked data is the other half. Without considering the consuming part of linked data, it is not possible to reap all of the benefits linked data has to offer.

No primer on linked data would be complete without the inclusion of the famous LOD cloud diagram, below:

[INSERT LOD CLOUD DIAGRAM HERE.]

While the diagram has not been updated in a few years, it represents the sets of published linked data available. It also illustrates how they relate to each other. As you can see DBedia is at the center of the cloud and illustrates how other data sets rely on it for (some)

\textsuperscript{15} Open Knowledge Foundation - \url{http://okfn.org}

------------------------

28 of 121
data and information. Many, if not all, of these sets of RDF have been registered in a directory called Datahub.\textsuperscript{16} There one can search and browse for all sorts of data sets access via linked data standards as well as other protocols. Datahub is a good place to look for complementary data sets to your own.

It is not possible for anybody to completely describe any collection of data. All data and information is inextricably linked to other data and information. There is not enough time nor energy in the world for any individual nor discrete group to do all the work. By harnessing the collective power of the Web (and linked data), it is possible to create more complete collections and more thorough description. These more complete collections and more complete descriptions can be created in two different ways. The first has already been described -- through the judicious use of shared URIs. The second is by harvesting linked data from other locations, combining it with your own, and producing value-added services against the result. Two excellent examples come to mind:

- **LIBRIS** (http://libris.kb.se) - This is the joint catalog of the Swedish academic and research libraries. Search results are presented in HTML, but the URLs pointing to individual items are really actionable URIs resolvable via content negotiation, thus support distribution of bibliographic information as RDF.

- **ReLoad** (http://labs.regesta.com/progettoReload/en) - This is a collaboration between the Central State Archive of Italy, the Cultural Heritage Institute of Emilia Romagna Region, and Regesta.exe. It is the aggregation of EAD files from a number of archives which have been transformed into RDF and made available as linked data. Its purpose and intent are very similar to the the purpose and intent of the combined LOCAH Project and Linking Lives.

A number of other example projects are listed in one of the Guidebooks's appendices.

\textsuperscript{16} Datahub - http://datahub.io
About linked data, a review

"About Rome, a review"

Many guidebooks about linked data and RDF start out with an elaboration of Tim Berner-Lee’s guidelines, but providing it now, in this part of the guide, may be more useful now that some of underlying principles have been described.

In "Linked Data -- Design Issues" Berners-Lee outlined four often-quoted expectations for implementing the Semantic Web. Each of these expectations are listed below along with some elaborations:

• "Use URIs as names for things" - URIs (Universal Resource Identifiers) are unique identifiers, and they are expected to have the same shape as URLs (Universal Resource Locators). These identifiers are expected to represent things such as people, places, institutions, concepts, books, etc. URIs are monikers or handles for real world or imaginary objects.

• "Use HTTP URIs so that people can look up those names." - The URIs are expected to look and ideally function on the World Wide Web through the Hypertext Transfer Protocol (HTTP), meaning the URI's point to things on Web servers.

• "When someone looks up a URI, provide useful information, using the standards (RDF, SPARQL)" - When URIs are sent to Web servers by Web browsers (or "user-agents" in HTTP parlance), the response from the server should be in a conventional, computer readable format. This format is usually a "serialization" of RDF (Resource Description Framework) -- a notation looking much like a rudimentary sentence composed of a subject, predicate, and object.

• "Include links to other URIs. So that they can discover more things." - Simply put, try very hard to use URIs other people have have used. This way the relationships you create can literally be linked to the relationships other people have created. These links may represent new knowledge.
In the same text Berners-Lee also outlined a sort of reward system -- a sets of stars -- for levels of implementation. This reward system also works very well as a strategy for publishing linked data by cultural heritage institutions such as archives. A person gets:

- one star for making data available on the web (in whatever format) but with an open license
- two stars for making the data machine-readable and structured data (e.g. Excel instead of an image scan of a table)
- three stars for making the data available in a non-proprietary format (e.g. comma-separated values instead of Excel)
- four stars for using open standards from W3C (RDF and SPARQL) to identify things, so that people can point at your stuff
- five stars for linking your data to other people's data to provide context

Implementing linked data represents a different, more modern way of accomplishing some of the same goals of archival science. It is a process of making more people aware of your archival description. It is not the only way to make more people aware, but it represents a way that will be widespread, thorough, and complete.

Linked data, or more recently referred to as "linked open data", is a proposed technique for generating new knowledge. It is intended to be a synergy between people and sets of agreed upon computer systems that when combined will enable both people and computers to discover and build relationships between seemingly disparate data and information to create and discover new knowledge.

In a nutshell, this is how it works. People possess data and information. They encode that data and information in any number of formats easily readable by computers. They then make the encoded data and information available on the Web. Computers are then employed to systematically harvested the encoded data. Since the data is easily readable, the computers store the data locally and look for similarly

-------------------------
31 of 121
encoded things in other locally stored data sets. When similar items are identified relationships can be inferred between the items as well as the other items in the data set. To people, some of these relationships may seem obvious and "old hat". On the other hand, since the data sets can be massive, relationships that were never observed previously may come to light, thus new knowledge is created.

Some of this knowledge may be trivial. For example, there might be a data set of places -- places from all over the world including things like geographic coordinates, histories of the places, images, etc. There might be another data set of people. Each person may be described using their name, their place of birth, and a short biography. These data sets may contain ten's of thousands of items each. Using linked data it would be possible to cross reference the people with the places to discover who might have met whom when and where. Some people may have similar ideas, and those ideas may have been generated in a particular place. Linked data may help in discovering who was in the same place at the same time and the researcher may be better able to figure out how a particular idea came to fruition.

The amount of data and information accessible today is greater in size than it has ever been in human history. Using our traditional techniques of reading, re-reading, writing, discussing, etc. is more than possible to learn new things about the state of the world, the universe, and the human condition. By exploiting the current state of computer technology is possible to expand upon our traditional techniques and possibly accelerate the mass of knowledge.

When you hear of linked data and the Semantic Web, the next thing you often hear is "RDF" or "Resource Description Framework". First and foremost, RDF is a way of representing information -- a data model. It does this through the use of assertions (think, "sentences") with only three parts: 1) a subject, 2) a predicate, and 3) an object. Put together, these three things create things called "triples".

RDF is not to be confused with RDF/XML or any other type of RDF "serialization". Remember, RDF describes triples, but it does not specify how the triples are express or written down. On the other hand, RDF/XML is an XML syntax for expressing RDF. Some people think RDF/XML is too complicated and too verbose. Consequently, other serializations have manifested themselves including N3 and Turtle.
Linked data is a process. It is a process of making information easily accessible and inextricably tied to the way the Web works. By making information available as linked data, you will more easily make your available to others and vice versa. The result will be value-added services and increased visibility.

Benefits

Archives are about collecting, organizing, preserving, and disseminating original, unique, and primary literature. These are the what's of archival practice, but the how's of archival practice evolve with the changing technology. With the advent of ubiquitous networked computing, people's expectations regarding access to information and knowledge have changed significantly. Unless institutions like archives change with the times, then the needs previously filled by archives will be filled by other institutions. Linked data is a how of archival practice, and it is one of those changes behooving archives to adopt. It is a standards-based technique for making data and information available on the Web. It is rooted in the very fabric of the Web and therefore is not beholden to any particular constituency. It is a long lasting standard and practice that will last as long as the hypertext transfer protocol is operational.

Making archival descriptions and collection available via linked data will increase the use of those descriptions and collections. It is a form of benign advertising. Commercial search engines will harvest the linked data and make it available in their search engines. Search engines will return hits to your descriptions and collections driving traffic to you and your site. Digital humanists will harvest your linked data, perform analysis against it, and create new knowledge or bring hidden knowledge to light. Computer scientist will collect your data, amalgamate it with the data of others, and discover relationship previously unconceived.

You can divide your combined collections and services into two tangible parts: 1) the collections themselves, and 2) the metadata describing them. It is usually possible to digitize your collections, but the result is rarely 100% satisfactory. Digitization is almost always a useful surrogate not a complete replacement. In this way, your collections as physical objects will always be a draw to all
types of learners and researchers. The metadata, on the other hand, is 100% digitizable, and therefore lends itself very well to dissemination on the Internet. Linked data represents one way to make this happen.

Few archival collections are 100% complete. There are always pieces missing, and some of those missing pieces will be owned by others. Your collections will have relationship with other collection, but you will not have direct access to those other collections. Some of these relationships are explicit. Some of them are implicit. If everybody were to expose their metadata then those explicit and implicit relationships can become more apparent. Once these relationships are strengthened and become more obvious, interest in the collections will increase accordingly, and the collections will be used to a greater degree. With this increased use will come increased attention, and in turn, a greater measure of success for the collections and services it provides.

"Rome is a large city that keeps getting larger. It is built on rich traditions, and the city continues to evolve. The language of the Romans expressive, and people speak with more than just words. They also speak with their hands. There are many ways to enjoy Rome. Different areas will appeal to different people, but to really understand Rome as a whole, a person need to visit and appreciate each of them in turn."
Strategies for putting linked data into practice

"If you go to Rome for a day, then walk to the Colosseum and Vatican City. Everything you see along the way will be extra. If you go to Rome for a few days, do everything you would do in a single day, eat and drink in a few cafes, see a few fountains, and go to a museum of your choice. For a week, do everything you would do in a few days, and make one or two day-trips outside Rome in order to get a flavor of the wider community. If you can afford two weeks, then do everything you would do in a week, and in addition befriend somebody in the hopes of establishing a life-long relationship."

When you read a guidebook about Rome -- or any travel guidebook -- there are simply too many listed things to see & do. Nobody can see all the sites, visit all the museums, walk all the tours, nor eat at all the restaurants. It is literally impossible to experience everything a place like Rome has to offer. So it is with linked data. Despite this fact, if you were to do everything linked data had to offer, then you would do all of things on the following list starting at the first item, going all the way down to evaluation, and repeating the process over and over:

1. design the structure your URIs
2. select/design your ontology & vocabularies -- model your data
3. map and/or migrate your existing data to RDF
4. publish your RDF as linked data
5. create a linked data application
6. harvest other people's data and create another application
7. evaluate
8. repeat

Given that it is quite possible you do not plan to immediately dive head-first into linked data, you might begin by getting your feet wet or dabbling in a bit of experimentation. That being the case, here are a number of different "itineraries" for linked data implementation. Think of them as strategies. They are ordered from least costly and most modest to greatest expense and completest execution:

1. Rome in a day - Maybe you can't afford to do anything right now, but if you have gotten this far in the
guidebook, then you know something about linked data. Discuss (evaluate) linked data with your colleagues, and consider revisiting the topic a year.

2. Rome in three days - If you want something relatively quick and easy, but with the understanding that your implementation will not be complete, begin migrating your existing data to RDF. Use XSLT to transform your MARC or EAD files into RDF serializations, and publish them on the Web. Use something like OAI2RDF to make your OAI repositories (if you have them) available as linked data. Use something like D2RQ to make your archival description stored in databases accessible as linked data. Create a triple store and implement a SPARQL endpoint. As before, discuss linked data with your colleagues.

3. Rome in week - Begin publishing RDF, but at the same time think hard about and document the structure of your future RDF's URIs as well as the ontologies & vocabularies you are going to use. Discuss it with your colleagues. Migrate and re-publish your existing data as RDF using the documentation as a guide. Re-implement your SPARQL endpoint. Discuss linked data not only with your colleagues but with people outside archival practice.

4. Rome in two weeks - First, do everything you would do in one week. Second, supplement your triple store with the RDF of others'. Third, write applications against the triple store that goes beyond search. These services will be of two types: services for curating the collection information, and services for using the collection. The former services are primarily for archivists and subject specialists. The later services are primarily intended for everybody from the general public to the academic scholar. These services will be akin to the telling of stories, and you will be discussing linked data with the world, literally.

Rome in a day
"If you to go to Rome for a day, then walk to the Colosseum and Vatican City. Everything you see along the way will be extra."

Linked data is not a fad. It is not a trend. It makes a lot of computing sense, and it is a modern way of fulfilling some the goals of archival practice. Just like Rome, it is not going away. An understanding of what linked data has to offer is akin to experiencing Rome first hand. Both will ultimately broaden your perspective. Consequently it is a good idea to make a concerted effort to learn about linked data, as well as visit Rome at least once. Once you have returned from your trip, discuss what you learned with your friends, neighbors, and colleagues. The result will be enlightening everybody.

The previous sections of this book described what linked data is and why it is important. The balance of book describes more of the how's of linked data. For example, there is a glossary to help reenforce your knowledge of the jargon. You can learn about HTTP "content negotiation" to understand how actionable URIs can return HTML or RDF depending on the way you instruct remote HTTP servers. RDF stands for "Resource Description Framework", and the "resources" are represented by URIs. A later section of the book describes ways to design the URIs of your resources. Learn how you can transform existing metadata records like MARC or EAD into RDF/XML, and then learn how to put the RDF/XML on the Web. Learn how to exploit your existing databases (such as the one's under Archon, Archivist's Toolkit, or ArchiveSpace) to generate RDF. If you are the Do It Yourself type, then play with and explore the guidebook's tool section. Get the gentlest of introductions to searching RDF using a query language called SPARQL. Learn how to read and evaluate ontologies & vocabularies. They are manifested as XML files, and they are easily readable and visualizable using a number of programs. Read about and explore applications using RDF as the underlying data model. There are a growing number of them. The book includes a complete publishing system written in Perl, and if you approach the code of the publishing system as if it were a theatrical play, then the "scripts" read liked scenes. (Think of the scripts as if they were a type of poetry, and they will come to life. Most of the "scenes" are less than a page long. The poetry even includes a number of refrains. Think of the publishing system as if it were a one act play.) If you want to read more, and you desire a vetted list of books and articles, then a later section lists a set of further reading.
After you have spent some time learning a bit more about linked data, discuss what you have learned with your colleagues. There are many different aspects of linked data publishing, such as but not limited to:

- allocating time and money
- analyzing the RDF of yours as well as others
- articulating policies
- cleaning and improving RDF
- collecting and harvesting the RDF of others
- deciding what ontologies & vocabularies to use
- designing local URIs
- enhancing RDF triples stores by asserting additional relationships
- finding and identifying URIs for the purposes of linking
- making RDF available on the Web (SPARQL, RDFa, data dumps, etc.)
- project management
- provisioning value-added services against RDF (catalogs, finding aids, etc.)
- storing RDF in triple stores

In archival practice, each of these things would be done by different sets of people: archivists & content specialists, administrators & managers, computer programers & systems administrators, metadata experts & catalogers. Each of these sets of people have a piece of the publishing puzzle and something significant to contribute to the work. Each of these sets of people plays a key and indispensable role in linked data publishing:
archivists & content specialists - These are the people who understand the "aboutness" of a particular collection. These are the people who understand and can thoroughly articulate the significance of a collection. They know how and why particular things belong in a collection. They are able to answer questions about the collection as well as tell stories against it.

administrators & managers - These are "resource allocators". They are people who manage time and money. They are people who establish priorities on an institutional level. They are expected to be financially aware and politically savvy. These people will have a view of the wider environment, have their finger on the pulse of where the local institution is moving, and be able to juggle seemingly conflicting directives. More than anybody else, they are expected to be able to outline a plan and see it to fruition.

metadata specialists & catalogers - These are people who understand data about data. Not only do they understand the principles of controlled vocabularies and authority lists, but they are also familiar with a wide variety of such lists, specifically as they are represented on the Web. In linked data there are fewer descriptive cataloging "rules". Nevertheless, the way the ontologies of linked data can be used need to be interpreted, and this interpretation needs to be consistent. Metadata specialists understand these principles.

computer programmers & systems administrators - Not only are these the people who have a fundamental understanding of what computer can and cannot do, but they also know how to put this understanding into practice. At the very least, the computer technologists need to understand a myriad of data structures and how to convert them into different data structures. Converting MARC 21 into MARCXML. Transforming EAD into HTML. Reporting against a relational database to create serialized RDF. These tasks required computer programming skills, but not necessarily any one in particular. Any modern programming language
(Java, PHP, Python, Ruby, etc.) includes the necessary function to complete the tasks.

Read about linked data. Learn about linked data. Bring these sets of people together discuss what you have learned. With this in mind, articulate some goals – broad targets of things you would like to accomplish. Some of them might include:

• making your archival collections more widely accessible
• working with others to build virtual collections of like topics or formats
• incorporating your archival descriptions into public spaces like Wikipedia
• integrating your collections into local teaching, learning, and research activities
• increasing the awareness of your archive to benefactors
• increasing the computer technology skills of fellow archivists

The what of your objectives are not so much identified with nouns as they are action verbs, such as: write, evaluate, implement, examine, purchase, hire, prioritize, list, delete, acquire, discuss, share, find, compare & contrast, stop, start, complete, continue, describe, edit, updated, create, purchase, upgrade, etc. The what of your objective is in the doing.

After discussing these sorts of issues, at the very least you will have a better collective understanding of the possibilities. If you don't plan to "go to Rome" right away, you might decide to reconsider the "vacation" at another time.

"Even Michelangelo, when he painted the Sisten Chapel, worked with a team of people each possessing a complementary set of skills. Each had something different to offer, and the discussion between themselves was key to their success."
Rome in three days

"If you to go to Rome for a few days, do everything you would do in a single day, eat and drink in a few cafes, see a few fountains, and go to a museum of your choice."

Linked data in archival practice is not new. Others have been here previously. You can benefit from their experience and begin publishing linked data right now using tools with which you are probably already familiar. For example, you probably have EAD files, sets of MARC records, or metadata saved in database applications. Using existing tools, you can transform this content into RDF and put the result on the Web, thus publishing your information as linked data.

At its very root, linked data is about making your data available for others to harvest and use. While the "killer linked data application" has seemingly not reared its head, this does not mean you ought not make your data available at linked data. You won't see the benefits immediately, but sooner or later (less than 5 years from now), you will see your content creeping into the search results of Internet indexes, into the work of both computational humanists and scientists, and into the hands of esoteric hackers creating one-off applications. Internet search engines will create "knowledge graphs", and they will include links to your content. The humanists and scientists will operate on your data similarly. Both will create visualizations illustrating trends. They will both quantifiably analyze your content looking for patterns and anomalies. Both will probably create network diagrams demonstrating the flow and interconnection of knowledge and ideas through time and space. The humanist might do all this in order to bring history to life or demonstrate how one writer influenced another. The scientist might study ways to efficiently store your data, easily move it around the Internet, or connect it with data set created by their apparatus. The hacker (those are the good guys) will create flashy-looking applications that many will think are weird and useless, but the applications will demonstrate how the technology can be exploited. These applications will inspire others, be here one day and gone the next, and over time, become more useful and sophisticated.

EAD
If you have used EAD to describe your collections, then you can easily make your descriptions available as valid linked data, but the result will be less than optimal. This is true not for a lack of technology but rather from the inherent purpose and structure of EAD files.

A few years ago an organization in the United Kingdom called the Archive's Hub was funded by a granting agency called JISC to explore the publishing of archival descriptions as linked data. The project was called LOCAH. One of the outcomes of this effort was the creation of an XSL stylesheet (ead2rdf) transforming EAD into RDF/XML. The terms used in the stylesheet originate from quite a number of standardized, widely accepted ontologies, and with only the tiniest bit configuration / customization the stylesheet can transform a generic EAD file into valid RDF/XML for use by anybody. The resulting XML files can then be made available on a Web server or incorporated into a triple store. This goes a long way to publishing archival descriptions as linked data. The only additional things needed are a transformation of EAD into HTML and the configuration of a Web server to do content negotiation between the XML and HTML.

For the smaller archive with only a few hundred EAD files whose content does not change very quickly, this is a simple, feasible, and practical solution to publishing archival descriptions as linked data. With the exception of doing some content negotiation, this solution does not require any computer technology that is not already being used in archives, and it only requires a few small tweaks to a given workflow:

1. implement a content negotiation solution
2. create and maintain EAD file
3. transform EAD into RDF/XML
4. transform EAD into HTML
5. save the resulting XML and HTML files on a Web server

---

17 LOCAH - http://archiveshub.ac.uk/locah/
18 ead2rdf - http://data.archiveshub.ac.uk/xslt/ead2rdf.xsl
EAD is a combination of narrative description and a hierarchal inventory list, and this data structure does not lend itself very well to the triples of linked data. For example, EAD headers are full of controlled vocabularies terms but there is no way to link these terms with specific inventory items. This is because the vocabulary terms are expected to describe the collection as a whole, not individual things. This problem could be overcome if each individual component of the EAD were associated with controlled vocabulary terms, but this would significantly increase the amount of work needed to create the EAD files in the first place.

The common practice of using literals to denote the names of people, places, and things in EAD files would also need to be changed in order to fully realize the vision of linked data. Specifically, it would be necessary for archivists to supplement their EAD files with commonly used URIs denoting subject headings and named authorities. These URIs could be inserted into id attributes throughout an EAD file, and the resulting RDF would be more linkable, but the labor to do so would increase, especially since many of the named items will not exist in standardized authority lists.

Despite these shortcomings, transforming EAD files into some sort of serialized RDF goes a long way towards publishing archival descriptions as linked data. This particular process is a good beginning and outputs valid information, just information that is not as linkable as possible. This process lends itself to iterative improvements, and outputting something is better than outputting nothing. But this particular process is not for everybody. The archive whose content changes quickly, the archive with copious numbers of collections, or the archive wishing to publish the most complete linked data possible will probably not want to use EAD files as the root of their publishing system. Instead some sort of database application is probably the best solution.

MARC

In some ways MARC lends itself very well to being published via linked data, but in the long run it is not really a feasible data structure.
Converting MARC into serialized RDF through XSLT is at least a two step process. The first step is to convert MARC into MARCXML and then MARCXML into MODS. This can be done with any number of scripting languages and toolboxes. The second step is to use a stylesheet such as the one created by Stefano Mazzocchi to transform the MODS into RDF/XML -- mods2rdf. From there a person could save the resulting XML files on a Web server, enhance access via content negotiation, and called it linked data.

Unfortunately, this particular approach has a number of drawbacks. First and foremost, the MARC format had no place to denote URIs; MARC records are made up almost entirely of literals. Sure, URIs can be constructed from various control numbers, but things like authors, titles, subject headings, and added entries will most certainly be literals ("Mark Twain", "Adventures of Huckleberry Finn", "Bildungsroman", or "Samuel Clemans"), not URIs. This issue can be overcome if the MARCXML were first converted into MODS and URIs were inserted into id or xlink attributes of bibliographic elements, but this is extra work. If an archive were to take this approach, then it would also behoove them to use MODS as their data structure of choice, not MARC. Continually converting from MARC to MARCXML to MODS would be expensive in terms of time. Moreover, with each new conversion the URIs from previous iterations would need to be re-created.

EAC-CPF

Encoded Archival Context for Corporate Bodies, Persons, and Families (EAC-CPF) goes a long way to implementing a named authority database that could be linked from archival descriptions. These XML files could easily be transformed into serialized RDF and therefore linked data. The resulting URIs could then be incorporated into archival descriptions making the descriptions richer and more complete. For example the FindAndConnect site in Australia uses EAC-CPF under the

20 EAC-CPF - http://eac.staatsbibliothek-berlin.de/
hood to disseminate information about people in its collection.\textsuperscript{21} Similarly, "SNAC aims to not only make the [EAC-CPF] records more easily discovered and accessed but also, and at the same time, build an unprecedented resource that provides access to the socio-historical contexts (which includes people, families, and corporate bodies) in which the records were created".\textsuperscript{22} More than a thousand EAC-CPF records are available from the RAMP project.\textsuperscript{23}

METS, MODS, OAI-PMH service providers, and perhaps more

If you have archival descriptions in either of the METS or MODS formats, then transforming them into RDF is as far away as your XSLT processor and a content negotiation implementation. As of this writing there do not seem to be any METS to RDF stylesheets, but there are a couple stylesheets for MODS. The biggest issue with these sorts of implementations are the URIs. It will be necessary for archivists to include URIs into as many MODS id or xlink attributes as possible. The same thing holds true for METS files except the id attribute is not designed to hold pointers to external sites.

Some archives and libraries use a content management system called ContentDM.\textsuperscript{24} Whether they know it or not, ContentDM comes complete with an OAI-PMH (Open Archives Initiative - Protocol for Metadata Harvesting) interface. This means you can send a REST-ful URL to ContentDM, and you will get back an XML stream of metadata describing digital objects. Some of the digital objects in ContentDM (or any other OAI-PMH service provider) may be something worth exposing as linked data, and this can easily be done with a system called oai2lod.\textsuperscript{25} It is a particular implementation of D2RQ, described below, and works quite well. Download application. Feed oai2lod the "home page" of the OAI-PMH service provider, and oai2load will publish the

\textsuperscript{21} FindAndConnect - http://www.findandconnect.gov.au

\textsuperscript{22} SNAC - http://socialarchive.iath.virginia.edu

\textsuperscript{23} RAMP - http://demo.rampeditor.info/export.php

\textsuperscript{24} ContentDM - http://www.contentdm.org

\textsuperscript{25} oai2lod - https://github.com/behas/oai2lod
OAI-PMH metadata as linked open data. This is another quick & dirty way to get started with linked data.

Databases

Publishing linked data through XML transformation is functional but not optimal. Publishing linked data from a database comes closer to the ideal but requires a greater amount of technical computer infrastructure and expertise.

Databases -- specifically, relational databases -- are the current best practice for organizing data. As you may or may not know, relational databases are made up of many tables of data joined together with keys. For example, a book may be assigned a unique identifier. The book has many characteristics such as a title, number of pages, size, descriptive note, etc. Some of the characteristics are shared by other books, like authors and subjects. In a relational database these shared characteristics would be saved in additional tables, and they would be joined to a specific book through the use of unique identifiers (keys). Given this sort of data structure, reports can be created from the database describing its content. Similarly, queries can be applied against the database to uncover relationships that may not be apparent at first glance or buried in reports. The power of relational databases lies in the use of keys to make relationships between rows in one table and rows in other tables. The downside of relational databases as a data model is infinite variety of fields/table combinations making them difficult to share across the Web.

Not coincidently, relational database technology is very much the way linked data is expected to be implemented. In the linked data world, the subjects of triples are URIs (think database keys). Each URI is associated with one or more predicates (think the characteristics in the book example). Each triple then has an object, and these objects take the form of literals or other URIs. In the book example, the object could be "Adventures Of Huckleberry Finn" or a URI pointing to Mark Twain. The reports of relational databases are analogous to RDF serializations, and SQL (the relational database query language) is analogous to SPARQL, the query language of RDF triple stores. Because of the close similarity between well-designed relational databases and linked data principles, the publishing of linked data directly from
relational databases makes whole lot of sense, but the process requires the combined time and skills of a number of different people: content specialists, database designers, and computer programmers. Consequently, the process of publishing linked data from relational databases may be optimal, but it is more expensive.

Thankfully, many archivists probably use some sort of behind the scenes database to manage their collections and create their finding aids. Moreover, archivists probably use one of three or four tools for this purpose: Archivist's Toolkit, Archon, ArchivesSpace, or PastPerfect. Each of these systems have a relational database at their heart. Reports could be written against the underlying databases to generate serialized RDF and thus begin the process of publishing linked data. Doing this from scratch would be difficult, as well as inefficient because many people would be starting out with the same database structure but creating a multitude of varying outputs. Consequently, there are two alternatives. The first is to use a generic database application to RDF publishing platform called D2RQ. The second is for the community to join together and create a holistic RDF publishing system based on the database(s) used in archives.

D2RQ is a very powerful software system.²⁶ It is supported, well-documented, executable on just about any computing platform, open source, focused, functional, and at the same time does not try to be all things to all people. Using D2RQ it is more than possible to quickly and easily publish a well-designed relational database as RDF. The process is relatively simple:

1. download the software
2. use a command-line utility to map the database structure to a configuration file
3. edit the configuration file to meet your needs
4. run the D2RQ server using the configuration file as input thus allowing people or RDF user-agents to search and browse the database using linked data principles

²⁶ D2RQ - http://d2rq.org
5. alternatively, dump the contents of the database to an RDF serialization and ingest the result into your favorite RDF triple store

The downside of D2RQ is its generic nature. It will create an RDF ontology whose terms correspond to the names of database fields. These field names do not map to widely accepted ontologies & vocabularies and therefore will not interact well with communities outside the ones using a specific database structure. Still, the use of D2RQ is quick, easy, and accurate.

Triple stores and SPARQL endpoints

Publishing your RDF as static files is relatively easy, but in order to really take advantage of your efforts you will want to additionally save your RDF in a triple store. There are many open source and commercial applications from which to choose. They all come with a set of specialized features, but they all work essentially the same way. Install. Configure. Run application to ingest RDF. Use different functions to edit and report on the contents of the triple store. Comparing & contrasting each of the available triple stores is beyond the scope of this document, but at the very least, look for one that provides access via a SPARQL endpoint. SPARQL is the query language of RDF triple stores, but the query language goes beyond the generation of lists. It can also be used to assert new RDF statement and have them saved to the store. It provides the means for answering Boolean questions or performing mathematical functions. Consequently, SPARQL can be used to not only search for information but also create new information and answer real-world collections.

Simply publishing RDF as static files is only half of the problem to be solved. By saving your RDF in a triple store and providing access to it via a SPARQL endpoint you open yourself up to possibilities that go beyond the dissemination of finding aids and description. Creating triple stores of your RDF (as well as the RDF of others) enable to tell more compelling stories and succinctly answer given questions.

Talk with your colleagues
Do not keep your candle hidden beneath a bushel basket. Tell your colleagues about your accomplishments. Write about your experience and share it via mailing lists, blog posting, conference presentations, formally published articles, and book. Through the writing process you will become more aware of both your successes as well as your failures. Others will see what you have done and offer comments. Some will follow your lead. Others will take your lead and go further. In any case, the dialog about linked data -- in terms of both its strengths & weaknesses -- will grow louder. Such dialog can only be a good thing. More useful techniques will be come best practices, and less useful techniques will fade from existence. Dialogue builds community, and communities can become very strong. A particular proverb comes to mind. "If you want to go fast, then go alone. If you want to go far, take your friends." Work in the sphere of linked data is exactly like this. Manifesting your archival description by transforming EAD into RDF is all well and good. It is fast & easy, but if you want to truly take advantage of the "linking" in linked data, then you will need to talk with your colleagues -- both in and out of archives -- in order to take things to another level.

"If you are going to be in Rome for only a few days, you will want to see the major sites, and you will want to adventure out & about a bit, but at the same time it will be a wise idea to follow the lead of somebody who has been there previously. Take the advise of these people. It is an efficient way to see some of the sights."

Rome in week

"For a week, do everything you would do in a few days, and make one or two day-trips outside Rome in order to get a flavor of the wider community."

In this "itinerary" you begin publishing RDF, but at the same time you actively design and document URIs as well as select ontologies & vocabularies for your RDF. You then re-publish your existing data using your documentation as a guide. And you re-implement your SPARQL endpoint. Discuss linked data not only with your colleagues but with people outside archival practice. This particular strategy is probably the most difficult it requires a lot of re-thinking about archival practice and ways it can be manifested. To these ends, there are three
books of particular interest to the reader. Think of them as required reading:

1. Linked data: Evolving the Web into a global data space by Tom Heath and Christian Bizer\(^\text{27}\) - This book provides a thorough and up-to-date overview of what linked data is and why it is important. It is full of useful examples and recipes for implementation.

2. Semantic Web for the working ontologist: Effective modeling in RDFS and OWL by Dean Allemang and James Hendler\(^\text{28}\) - This book is primarily intended for people who are evaluating and designing ontologies & vocabularies. It compares & contrasts RDF to alternative data models (like spreadsheets or relational databases), and explains why RDF is particularly suitable to the Web. It then outlines how to create one's own ontology.

3. Linked data patterns: A Pattern catalogue for modeling, publishing, and consuming linked data by Leigh Dodds and Ian Davis\(^\text{29}\) - As a "pattern catalog", this book is a long list of common problem experienced by people implementing linked data as well as accompanying discussion and solutions to the problems. The problems and solutions are divided into a number of categories: URIs (identifiers), modeling, publishing, data management, and applications.

Design your URIs

\(^{27}\) Linked data: Evolving the Web into a global data space by Tom Heath and Christian Bizer - [http://linkeddatabook.com](http://linkeddatabook.com)

\(^{28}\) Semantic Web for the working ontologist: Effective modeling in RDFS and OWL by Dean Allemang and James Hendler - [http://workingontologist.org](http://workingontologist.org)

\(^{29}\) Linked data patterns: A Pattern catalogue for modeling, publishing, and consuming linked data by Leigh Dodds and Ian Davis - [http://patterns.dataincubator.org](http://patterns.dataincubator.org)
The heart of linked data is the description of things. Things can be anything, either real or imaginary, and all of these things are expected to be represented by URIs. Consequently, when you are intending to publish linked data, you need to think about the structure of the identifiers of your things. To large degree URIs are expected to be "cool". This means they should not change and they should be:

- simple - short, human-readable without any name/value pairs, and easily depicted in written form
- stable - immutable, something that lasts two, twenty, or two hundred years, sans implementation bits such as file name extensions because file types (JPEG, PDF, etc.) change over time
- manageable - meaning you have some sort of system for dealing with implement changes behind the scenes; content negotiation systems and HTTP server management systems are keys to success

Pete Johnson, while designing the URIs for the "things" in LOCAH, articulated the following pattern for the URIs he was going to mint:

http://{domain}/id/{concept}/{reference}

Examples then included:

- http://example.org/id/findingaid/mums059
- http://example.org/id/family/clarkfamily
- http://example.org/id/repository/usUS-DLC

These URIs were derived from the data inside EAD files and took into account:

30 "cool" URIs - http://www.w3.org/TR/cooluris/

• local identifiers - URIs based embedded identifiers
• authority controlled values - building from the names in remote lists
• locally scoped names - building from the names in local lists
• locally developed "rules" - identifiers based on long strings of text
• identifier inheritance - URIs starting with local identifiers and building on hierarchy

These principles are not very much different from some of the Identifier Patterns articulated by Dodds and Davis. Patterns included:

• hierarchical URIs - these are "patterned" URIs denoting sub and super-class relationships
• literal keys - based on custom properties, such as a subclass if Dublin Core identifiers
• natural keys - URIs built from things like ISSN numbers, OCLC numbers, database keys, etc.
• patterned URIs - designed after predicable schemes, much like Johnson's examples
• proxy URIs - URIs created after some alignment is done against amalgamated RDF
• rebased URIs - a renamed URI done so because the previous one was not as "cool" as it could be
• shared keys - identifiers created across domains
• URL slugs - patterned URIs based based on strings

Designing your URIs is a bit of a chicken & egg problem. You are designing URIs for the "things" of your archival description, and
before you can create the URIs you need to know what "things" you have, which is the subject of the next section. On the other hand, the subjects and objects of RDF statements are expected to be URIs -- the identifiers you will be sharing -- the very heart of linked data. In other words, you need both URIs as well as ontologies & vocabularies at once and at the same time to do the work of linked data. They go hand-in-hand. You can not do one without the other.

At the very least remember one thing, design your URIs to be "cool".

Select your ontology & vocabularies

Articulate and implement best practices for publishing RDF - Work with your friends to articulate and document an "application profile". As guidelines and best practices get articulated, implement them by going back to Step #1. In the meantime, continue on to Step #4.

Republish your RDF

The second alternative requires community effort and coordination. The databases of Archivist's Toolkit, Archon, ArchivesSpace, or Past Perfect could be assumed. The community could then get together and decide on an RDF ontology to use for archival descriptions. The database structure(s) could then be mapped to this ontology. Next, programs could be written against the database(s) to create serialized RDF thus beginning the process of publishing linked data. Once that was complete, the archival community would need to come together again to ensure it uses as many shared URIs as possible thus creating the most functional sets of linked data. This second alternative requires a significant amount of community involvement and wide-spread education. It represents a never-ending process.

Publish your RDF -2. Publish RDF - No matter what kind of RDF you are able to create, make it available on the Web 1. Do simple publishing - At its very root, linked data is about making your data available for others to harvest and use. While the "killer linked data application" has seemingly not reared its head, this does not mean you ought not make your data available at linked data. You won't see the benefits immediately, but sooner or later (less than 5 years from now), you will see your content creeping into the search results of Internet
indexes, into the work of both computational humanists and scientists, and into the hands of esoteric hackers creating one-off applications. Internet search engines will create "knowledge graphs", and they will include links to your content. The humanists and scientists will operate on your data similarly. Both will create visualizations illustrating trends. They will both quantifiably analyze your content looking for patterns and anomalies. Both will probably create network diagrams demonstrating the flow and interconnection of knowledge and ideas through time and space. The humanist might do all this in order to bring history to life or demonstrate how one writer influenced another. The scientist might study ways to efficiently store your data, easily move it around the Internet, or connect it with data set created by their apparatus. The hacker (those are the good guys) will create flashy-looking applications that many will think are weird and useless, but the applications will demonstrate how the technology can be exploited. These applications will inspire others, be here one day and gone the next, and over time, become more useful and sophisticated.

Rome in two weeks

"If you can afford two weeks, then do everything you would do in a week, and in addition befriend somebody in the hopes of establishing a life-long relationship."

Now that you have significantly practiced with the principles of publishing linked data, it is time to harvest the RDF of others so you can enhance your archival services. To do this you will first continue to do everything in the previous sections. You will then supplement and enhance your triple store with the RDF and information of others'. Third, you will write applications against the triple store that go beyond search. These services will be of two types: 1) services for curating the collection of information, and 2) services for using the collection. The former services are primarily for archivists and metadata specialists. The later are primarily intended for everybody from the general public to the scholar. These services will be akin to the telling of stories, and once implemented you will be discussing linked data with the world, literally.

Supplement and enhance your triple store
RDF is published in many different ways such as but not limited to: as triple store dumps, via content negotiation on the other side of actionable URIs, embedded in HTML files as RDFa, available as the result of SPARQL queries, etc. Other metadata and information is available from other means such as REST-ful websites, OAI-PMH data providers, spreadsheets and databases from communities of interest. The information and metadata from each of these "places" can be identified and prioritized into some sort of collection development policy. For example, you might be interested in augmenting your RDF with the RDF of other archival collections. You might want to supplement your descriptions with images of people, places, and things. The places in your archival description may be enhanced with geographic coordinates. Controlled vocabularies in your description may be equivocated or related to other controlled vocabularies enabling the interlinking across collections. Whatever the reason, the harvesting and collecting of other people's metadata and information can only enrich the information services you provide.

Begin the harvesting process by taking advantages of directories of RDF and metadata sets. Datahub is a good example.\textsuperscript{32} Dumps of RDF could be mirrored locally and then ingested into the triple store. HTML pages could be crawled, RDFa extracted, and the resulting ingested into the triple store. Lists of actionable URIs could be created by searching remote websites. These actionable URIs could then be fed to a computer program which will use content negotiation to harvest the remote RDF. The actual harvesting process will almost definitely require the skills of a computer programmer or systems administrator. After remote metadata and RDF has been incorporated into your local triple store, you will want to continue to implement your local SPARQL endpoint, because you will definitely use SPARQL to implement the triple store curation services as well as the services for the general public and scholar.

Curating the collection

As additional information is brought into your triple store, there will be an increasing need to curate the information. This process is very similar, if not congruent with the processes behind a project of

\textsuperscript{32} Datahub - \url{http://datahub.io/}
a few years ago called the National Science Foundation Digital Library (NSDL). This project was intended to harvest data from across the Internet, amalgamate it, and provide services against the result. These services often included creating subsets of the data and search services on top of them. This curation process is similar to the collection / services processes undertaken by Europe's Europeana project and the Digital Public Library of America.

Once the metadata and information have been acquired there is a need to make it the "best" information possible. What does this mean? In this case, the word "best" connotes information that is: 1) consistent, 2) correct, 3) accurate, 4) complete, and 5) timely. The processes of maintaining metadata and information are just as ongoing and indeterminate as the curation of physical collection.

Creating and maintaining metadata is a never-ending process. The items being described can always use elaboration. Collections may increase in size. Rights applied against content may change. Things become digitized, or digitized things are migrated from one format to another. Because of these sorts of things and many others, cleanup, conversion, and consistency are something every metadata specialist needs to keep in mind. They are things to be managed and maintained as the linked data of others is assimilated into your own collection. These issues have been nicely elaborated upon in separate articles by Dianne Hillman and Thomas Johnson. Hillman outlines a number of problems:

1. missing data - metadata elements not present in supplied metadata
2. incorrect data - metadata values not conforming to standard element use

---

33 NSDL - https://nsdl.org

35 Recipes for Enhancing Digital Collections with Linked Data by Thomas Johnson and Karen Estlund - http://journal.code4lib.org/articles/9214

56 of 121
3. confusing data - multiple values crammed into a single metadata element, embedded HTML tags, etc.

4. insufficient data - no indication of controlled vocabularies used

Johnson similar things:

1. removing "noise" - removing named labels with no values (empty elements), removing statements with non-information whose values are things like "unknown" or "n/a", or values whose content is only punctuation

2. normalizing presentation - removing extraneous white spaces, removing HTML double encodings, normalizing the order of first names and last names, etc.

3. assigning URIs to curation objects - identifying URIs for string values, assigning URIs to digitized objects

4. mapping legacy elements to linked data vocabularies - for example, transforming any elements with values like "245" to some form of title

Linked data affords an additional type of enhancement -- enhancements of relationship and augmentation. RDF is made up of ontologies. Statements will be asserted and brought together in similar collection. One set of statements may use FOAF. Another may use Dublin Core. These two ontologies include the concept of names of people. You might want to make assertions in your RDF equivocating the names in FOAF with the names in Dublin Core. Similar things may be done with identifiers where URIs of this type are intended to be equivalent with the URIs of another type. For example, the URI denoting Mark Twain in VIAF may be equivalent to the URI RDF collection. By denoting equivalence between these two items additional information can be brought to bear regarding Mark Twain.

Cleanup, conversion, and consistency mean many things. Does all of your metadata use the same set of one or more vocabularies? Are things spelled correctly? Maybe you used abbreviations in one document but spelled things out in another? Have you migrated your JPEG images to JPEG2000 or TIFF formats? Maybe the EAD DTD has been updated, and you
want (need) to migrate your finding aids from one XML format to another? Do all of your finding aids exhibit the same level of detail; are some "thinner" than others? Have you used one form of a person's name in one document but used another form in a different document? The answers to these sorts of questions point to the need for cleanup, conversion, and consistency.

Is your archival description LOD-ready? Now? The simple, straight-forward answer is, "Yes." The longer and more complicated answer is, "No. Your data is never 100% linked data ready because the process of archival description is never finished."

Applications & use-cases

In the previous "tours of Rome", the creation of a simple search engine against your triple store was suggested. In those "itineraries" other applications could have been created, but now that additional metadata and information have been brought to light it will be behoove you to go beyond the simple search engine and begin to tell stories. If not, then the services you are providing aren't very much dissimilar to a search against Google. Here are a few application and use-case ideas.

Create a union catalog. This is really an enhancement of the simple search idea. If you make your data available as linked data, and if you find at least one other archive who is making their data available as linked data, then you can find a third somebody who will combine them into a triple store and implement a rudimentary SPARQL interface against the union. Once this is done a researcher could conceivably search the interface for a URI to see what is in both collections. The absolute imperative key to success for this to work is the judicious inclusion of URIs in both data sets. This scenario becomes even more enticing with the inclusion of two additional things. First, the more collections in the triple store the better. You can not have enough collections in the store. Second, the scenario will be even more enticing when each archive publishes their data using similar ontologies as everybody else. Success does not hinge on similar ontologies, but success is significantly enhanced. Just like the relational databases of today, nobody will be expected to query them using their native query language (SQL or SPARQL). Instead the interfaces will be much more user-friendly. The properties of classes
in ontologies will become facets for searching and browsing. Free text as well as fielded searching via drop-down menus will become available. As time goes on and things mature, the output from these interfaces will be increasingly informative, easy-to-read, and computable. This means the output will answer questions, be visually appealing, as well as be available in one or more formats for other computer programs to operate upon.

Tell a story. You and your hosting institution(s) have something significant to offer. It is not just about you and your archive but also about libraries, museums, the local municipality, etc. As a whole you are a local geographic entity. You represent something significant with a story to tell. Combine your linked data with the linked data of others in your immediate area. The ontologies will be a total hodgepodge, at least at first. Now provide a search engine against the result. Maybe you begin with local libraries or museums. If you work in an academic setting, then maybe you begin with other academic departments across campus. Allow people to search the interface and bring together the content of everybody involved. Do not just provide lists of links in search results, but instead create knowledge graphs. Supplement the output of search results with the linked data from Wikipedia, Flickr, etc. In a federated search sort of way, supplement the output with content from other data feeds such as (licensed) bibliographic indexes or content harvested from OAI-PMH repositories. Identify complementary content from further afield. Figure out a way for you and they to work together to create a newer, more complete set of content. Creating these sorts of things on-the-fly will be challenging. On the other hand, you might implement something that is more iterative and less immediate, but more thorough and curated if you were to select a topic or theme of interest, and do your own searching and story telling. The result would be something that is at once a Web page, a document designed for printing, or something importable into another computer program.

Create new knowledge. Create an inference engine, turn it against your triple store, and look for relationships between distinct sets of URIs that weren't previously apparent. Here's one way how:

1. allow the reader to select an actionable URI of personal interest, ideally a URI from the set of URIs you curate
2. submit it an HTTP server or SPARQL endpoint and request RDF as output

3. save the output to a local store

4. for each subject and object URI found the output, go to Step #2

5. go to step #2 n times for each newly harvested URI in the store where n is a reader-defined integer greater than 1; in other words, harvest more and more URIs, predicates, and literals based on the previously harvested URIs

6. create a set of human readable services / reports against the content of the store, and think of these services / reports akin to finding aids, reference materials, or museum exhibits of the future: Example services / reports might include:

   • hierarchal lists of all classes and properties - This would be a sort of semantic map. Each item on the map would be clickable allowing the reader to read more and drill down.

   • text mining reports - collect into a single "bag of words" all the literals saved in the store and create: word clouds, alphabetical lists, concordances, bibliographies, directories, gazetteers, tabulations of parts of speech, named entities, sentiment analyses, topic models, etc.

   • maps - use place names and geographic coordinates to implement a geographic information service

   • audio-visual mash-ups - bring together all the media information and create things like slideshows, movies, analyses of colors, shapes, patterns, etc.

   • search interfaces - implement a search interface against the result, SPARQL or otherwise
facts - remember SPARQL queries can return more than just lists. They can return mathematical results such as sums, ratios, standard deviations, etc. It can also return Boolean values helpful in answering yes/no questions. You could have a set of canned fact queries such as, how many ontologies are represented in the store. Is the number of ontologies greater than 3? Are there more than 100 names represented in this set? The count of languages used in the set, etc.

7. Allow the reader to identify a new URI of personal interest, specifically one garnered from the reports generated in Step #5.

8. Go to Step #2, but this time have the inference engine be more selective by having it try to crawl back to your namespace and set of locally curated URIs.

9. Return to the reader the URIs identified in Step #7, and by consequence, these URIs ought to share some of the same characteristics as the very first URI; you have implemented a "find more like this one" tool. You, as curator of the collection of URIs might have thought the relations between the first URI and set of final URIs was obvious, but those relationships would not necessarily be obvious to the reader, and therefore new knowledge would have been created or brought to light.

10. If there are no new URIs from Step #7, then go to Step #6 using the newly harvested content.

11. Done - if a system were created such as the one above, then the reader would quite likely have acquired some new knowledge, and this would be especially true the greater the size of n in Step #5.

Expand beyond the document centric finding aid model. The archival finding aid (specifically the EAD file) is essentially a document with two parts: 1) a narrative story describing a collection, and 2) an inventory of items in the collection. Yes, these finding aids are manifested as XML files, and therefore they are well-structured and
computer-readable, but they do not really take advantage of the "webbed" environment. Finding aids impose a conceptual model on a collection from the point of view of the archivist. This in an of itself is not a bad thing and it serves many purposes. At the same time, finding aids make it difficult to assert alternative conceptual models on the same collection. Like the MARC records of librarianship, EAD files are an electronic form of a print data model. MARC is to catalog cards as EAD is to finding aids. Each serves a particular purpose, but neither exploit nor really take advantage of computers connected through HTTP. Migrating archival description from document-centric finding aids to the more atomistic RDF makes it easier for many models to be asserted. It also overcomes a number of other limitations. The following use-cases are gleaned from the original LiAM proposal and can be addressed by manifesting archival description as linked data:

- An individual record or series of records often have simultaneous significance in multiple contexts. How do you signify simultaneous records when they might have multiple contexts? --Anne Sauer

- Record creators have multifaceted relationships to different records and series of records. How do you model record creators with different series of records? --Anne Sauer

- Documentation of a function often spans provenance-based records series. How do you link functions when provenance-based records span series? --Anne Sauer

- Documentation of an event often spans provenance-based records series. How do you link events when provenance-based records span series? --Anne Sauer

- Intentional filing systems are often no longer employed as a file management strategy, undermining the affordance of original order as a conceptual basis for description. How do you model the intentional filing system? --Anne Sauer

- Because women may change their names more frequently than men in Western culture, how do you create connections between collections due to different names for the same
person. An interesting example of scattered collections that would have been brought together are the William Cameron Blackett personal archive at the Harvard University Archives with two collections of papers of his daughter (Priscilla Blackett Dewey Houghton) described as the Priscilla B. Dewey papers at the Harvard Theatre Collection, Houghton Library and the papers of Priscilla Dewey Houghton at the Schlesinger Library. --Juliana Kuipers

- How do you account for migrating responsibility? Responsibility and authority for a particular administrative function may move from one office to another. For example, student discipline may move from a President's office to a Dean of a school, to the Dean of Students, and then to a disciplinary board. --Kate Bowers

- How do you account for multiple email addresses? Multiple aliases for the same email account may exist simultaneously, one person may have many email accounts. --Skip Kendall

"Going to Rome for two weeks means going beyond the usual tourist sights and really delving into the culture. By doing so you will learn of the wider world around you, break out any silos, and become a more active participant in a global conversation. Not only that, but you will be doing it in a more universal and timeless fashion."
Trends and gaps

"A funny thing happened on the way to the forum."

Two travelogues

Two recent professional meetings have taught me that - when creating some sort of information service - linked data will reside and be mixed with data collected from any number of Internet sites. Linked data interfaces will coexist with REST-ful interfaces, or even things as rudimentary as FTP. To the archivist, this means linked data is not the be-all and end-all of information publishing. There is no such thing. To the application programmer, this means you will need to have experience with a ever-growing number of Internet protocols. To both it means, "There is more than one way to get there."

In October of 2013 I had the opportunity to attend the Semantic Web In Libraries conference. It was a three-day event attended by approximately three hundred people who could roughly be divided into two equally sized groups: computer scientists and cultural heritage institution employees. The bulk of the presentations fell into two categories: 1) publishing linked data, and 2) creating information services. The publishers talked about ontologies, human-computer interfaces for data creation/maintenance, and systems exposing RDF to the wider world. The people creating information services were invariably collecting, homogenizing, and adding value to data gathered from a diverse set of information services. These information services were not limited to sets of linked data. They also included services accessible via REST-ful computing techniques, OAI-PMH interfaces, and there were probably a few locally developed file transfers or relational database dumps described as well. These people where creating lists of information services, regularly harvesting content from the services, writing cross-walks, locally storing the content, indexing it, providing services against the result, and sometimes republishing any number of "stories" based on the data. For the second group of people, linked data was certainly not the only game in town.

In February of 2014 I had the opportunity to attend a hackathon called GLAM Hack Philly. A wide variety of data sets were presented for "hacking" against. Some where TEI files describing Icelandic manuscripts. Some was linked data published from the British museum.
Some was XML describing digitized journals created by a vendor-based application. Some of it resided in proprietary database applications describing the location of houses in Philadelphia. Some of it had little or no computer-readable structure and described plants. Some of it was the wiki mark-up for local municipalities. After the attendees (there were about two dozen of us) learned about each of the data sets we self-selected and hacked away at projects of our own design. The results fell into roughly three categories: geo-referencing objects, creating searchable/browsable interfaces, and data enhancement. With the exception of the hack repurposing journal content into visual art, the results were pretty typical for cultural heritage institutions. But what fascinated me was way us hackers selected our data sets. Namely, the more complete and well-structured the data the more hackers gravitated towards it. Of all the data sets, the TEI files were the most complete, accurate, and computer-readable. Three or four projects were done against the TEI. (Heck, I even hacked on the TEI files.) The linked data from the British Museum – very well structured but not quite as through at the TEI – attracted a large number of hackers who worked together for a common goal. All the other data sets had only one or two people working on them. What is the moral to the story? There are two of them. First, archivists, if you want people to process your data and do "kewl" things against it, then make sure the data is thorough, complete, and computer-readable. Second, computer programmers, you will need to know a variety of data formats. Linked data is not the only game in town.

The technologies described in this Guidebook are not the only way to accomplish the goals of archivists wishing to make their content more accessible. Instead, linked data is just one of many protocols in the toolbox. It is open, standards-based, and simpler rather than more complex. On the other hand, other protocols exist which have a different set of strengths and weaknesses. Computer technologists will need to have a larger rather than smaller knowledge of various Internet tools. For archivists, the core of the problem is still the collection and description of content. This – a what of archival practice – continues to remain constant. It is the how of archival practice – the technology – that changes at a much faster pace.

With great interest I read the Spring/Summer issue of Information Standards Quarterly entitled "Linked Data in Libraries, Archives, and Museums" where there were a number of articles pertaining to linked
data in cultural heritage institutions. Of particular interest to me were the loosely enumerated challenges of linked data. Some of them included:

- the apparent Tower Of Babel when it comes to vocabularies used to describe content, and the same time we need to have "ontology mindfulness''.
- dirty, inconsistent, or wide varieties of data integrity
- persistent URIs
- the "chicken & egg" problem of why linked data if there is no killer application

There are a number of challenges in the linked data process. Some of them are listed below, and some of them have been alluded to previously. Create useful linked data, meaning, create linked that links to other linked data. Linked data does not live in a world by itself. Remember, the "l" stands for "linked". For example, try to include URIs that are the URIs used on other linked data sets. Sometimes this is not possible, for example, with the names of people in archival materials. When possible, they used VIAF, but other times they needed to create their own URI denoting an individual. There is a level of rigor involved in creating the data model, and there may be many discussions regarding semantics. For example, what is a creator? Or, when is a term intended to be an index term as opposed to a reference. When does one term in one vocabulary equal a different term in a different vocabulary? Balance the creation of your own vocabulary with the need to speak the language of others using their vocabulary. Consider "fixing" the data as it comes in or goes out because it might not be consistent nor thorough. Provenance is an issue. People – especially scholars – will want to know where the linked data came from and whether or not it is authoritative. How to solve or address this problem? The jury is still out on this one. Creating and maintaining linked data is difficult because it requires the skills of a number of different types of people. Computer programmers. Database designers. Subject experts. Metadata specialists. Archivists. Etc. A team is all but necessary.

---

Linked data represents a modern way of making your archival descriptions accessible to the wider world. In that light, it represents a different way of doing things but not necessary a different what of doing things. You will still be doing inventory. You will still be curating collections. You will still be prioritizing what goes and what stays.

Gaps

Linked data makes a lot of sense, but there are some personnel and technological gaps needing to be filled before it can really and truly be widely adopted by archives (or libraries or museums). They include but are not limited to: hands-on training, "string2URI" tools, database to RDF interfaces, mass RDF editors, and maybe "killer applications".

Hands-on training

Different people learn in different ways, and hands-on training on what linked data is and how it can be put into practice would go a long way towards the adoption of linked data in archives. These hands-on sessions could be as short as an hour or as long as one or two days. They would include a mixture of conceptual and technological topics. For example, there could be a tutorial on how to search RDF triple stores using SPARQL. Another tutorial would compare & contrast the data models of databases with the RDF data model. A class could be facilitated on how to transform XML files (MARCXML, MODS, EAD) to any number of RDF serializations and publish the result on a Web server. There could be a class on how to design URIs. A class on how to literally draw an RDF ontology would be a good idea. Another class would instruct people on how to formally read & write an ontology using OWL. Yet another hands-on workshop would demonstrate to participants the techniques for creating, maintaining, and publishing an RDF triple store. Etc. Linked data might be a "good thing", but people are going to need to learn how to work more directly with it. These hands-on trainings could be aligned with hack-a-thons, hack-fests, or THATCamps so a mixture of archivists, metadata specialists, and computer programmers would be in the same spaces at the same times.
There is a need for tools enabling people and computers to automatically associate string literals with URIs. If nobody (or relatively few people) share URIs across their published linked data, then the promises of linked data won't come to fruition. Archivists (and librarians and people who work in museums) take things like controlled vocabularies and name authority lists very seriously. Identifying the "best" URI for a given thing, subject term, or personal name is something the profession is going to want to do and do well.

Fabian Steeg and Pascal Christoph at the 2013 Semantic Web in Libraries conference asked the question, "How can we benefit from linked data without being linked data experts?" Their solution was the creation of a set of tools enabling people to query a remote service and get back a list of URIs which were automatically inserted into a text. This is an example of a "string2URI" tool that needs to be written and widely adopted. These tools could be as simple as a one-box, one-button interface where a person enters a word for phrase and one or more URIs are returned for selection. A slightly more complicated version would include a drop-down menu allowing the person to select places to query for the URI. Another application suggested by quite a number of people would use natural language to first extract named entities (people, places, things, etc.) from texts (like abstracts, scope notes, biographical histories, etc.). Once these entities were extracted, they would then be fed to string2URI. The LC Linked Data Service, VIAF, and Worldcat are very good examples of string2URI tools. The profession needs more of them. SNAC's use of EAC-CPF is a something to watch in this space.

Database to RDF publishing systems

37 LC Linked Data Service - http://id.loc.gov
38 VIAF - http://viaf.org
39 Worldcat - http://www.worldcat.org
40 SNAC - http://socialarchive.iath.virginia.edu
There are distinct advantages and disadvantages of the current ways of creating and maintaining the descriptions of archival collections. They fill a particular purpose and function. Nobody is going to suddenly abandon well-known techniques for ones seemingly unproven. Consequently, there is a need to easily migrate existing data to RDF. One way towards this goal is to transform or export archival descriptions from their current containers to RDF. D2RQ could go a long way towards publishing the underlying databases of PastPerfect, Archon, Archivist's Toolkit, or ArchivesSpace as RDF. A seemingly little used database to RDF modeling language -- R2RML -- could be used for similar purposes.\footnote{R2RML - http://www.w3.org/TR/r2rml/} These particular solutions are rather generic. Either a great deal of customizations needs to be done using D2RQ, or new interfaces to the underlying databases need to be created. Regarding the later, this will require a large amount of specialized work. An ontology & vocabulary would need to be designed or selected. The data and the structure of the underlying databases would need to be closely examined. A programmer would need to write reports against the database to export RDF and publish it in one form or another. Be forewarned. Software, like archival description, is never done. On the other hand, this sort of work could be done once and then shared with the wider archival community and then applied to local implementations of Archivist's Toolkit, ArchivesSpace, etc.

Mass RDF editors

Archivists curate physical collections as well as descriptions of those collections. Ideally, the descriptions would reside in a triple store as if it were a database. The store would be indexed. Queries could be applied against the store. Create, read, update, and delete operations could be easily done. As RDF is amassed it will almost definitely need to be massaged and improved. URIs may need to be equated. Controlled vocabulary terms may need to be related. Supplementary statements may need to be asserted enhancing the overall value of the store. String literals may need to be normalized or even added. This work will not be done on a one-by-one statement-by-statement basis. There are simply too many triples -- 100's of thousands, if not millions of them. Some sort of mass RDF editor will need to be created. If the store was well managed, and if a person was well-versed in SPARQL, then much of this work could be done through...
SPARQL statements. But SPARQL is not for the faint of heart, and despite what some people say, it is not easy to write. Tools will need to be created -- akin to the tools described by Diane Hillman and articulated through the experience with the National Science Foundation Digital Library -- making it easy to do large-scale additions and updates to RDF triple stores.

"Killer" applications

To some degree, the idea of the Semantic Web and linked data has been oversold. We were told, "Make very large sets of RDF freely available and new relationships between resources will be discovered." The whole thing smacks of artificial intelligence which simultaneously scares people and makes them laugh out loud. On the other hand, a close reading of Allemang's and Hendler's book Semantic Web For The Working Ontologist describes exactly how and why these new relationships can be discovered, but these discoveries do take some work and a significant volume of RDF from a diverse set of domains.

So maybe the "killer" application is not so much a sophisticated super-brained inference engine but something less sublime. A number of examples come to mind. Begin by recreating the traditional finding aid. Transform an EAD file into serialized RDF, and from the RDF create a finding aid. This is rather mundane and redundant but it will demonstrate and support a service model going forward. Go three steps further. First, create a finding aid, but supplement it with data and information from your other finding aids. Your collections do not exist in silos nor isolation. Supplement these second-generation finding aids with images, geographic coordinates, links to scholarly articles, or more thorough textual notes all discovered from outside linked data sources. Third, establish relationships between your archival collections and the archival collections outside your institution. Again, relationships could be created between collections and between items in the collections. These sorts of "killer" applications enables the archivist to stretch the definition of finding aid.

Another "killer" application may be a sort of union catalog. Each example of the union catalog will have some sort of common domain. The domain could be topical: Catholic studies, civil war history, the papers of a particular individual or organization. Collect the RDF
from archives of these domains, put it into a single triple store, clean up and enhance the RDF, index it, and provide a search engine against the index. The domain could be regional. For example, the RDF from an archive, library, and museum of an individual college or university could be created, amalgamated, and presented. The domain could be professional: all archives, all libraries, or all museums.

Another killer application, especially in an academic environment, would be the integration of archival description into course management systems. Manifest archival descriptions as RDF. Manifest course offerings across the academy in the form of RDF. Manifest student and instructor information as RDF. Discover and provide links between archival content and people in specific classes. This sort of application will make archival collections much more relevant to the local population.

Tell stories. Don't just provide links. People want answers as much as they want lists of references. After search queries are sent to indexes, provide search results in the form of lists of links, but also mash together information from search results into a "named graph" that includes an overview of the apparent subject queried, images of the subject, a depiction of where the subject is located, and few very relevant and well-respected links to narrative descriptions of the subject. You can see these sorts of enhancement in the results of many Google and Facebook search results.

Support the work of digital humanists. Amass RDF. Clean, normalize, and enhance it. Provide access to it via searchable and browsable interfaces. Provide additional services against the results such as timelines built from the underlying dates found in the RDF. Create word clouds based on statistically significant entities such as names of people or places or themes. Provide access to search results in the form of delimited files so the data can be imported into other tools for more sophisticated analysis. For example, support a search results to Omeka interface. For that matter, create an Omeka to RDF service.

The "killer" application for linked data is only as far away as your imagination. If you can articulate it, then it can probably be created.

Omeka - https://omeka.org

Last word

Linked data changes the way your descriptions get expressed and distributed. It is a lot like taking a trip across country. The goal was always to get to the coast to see the ocean, but instead of walking, going by stage coach, taking a train, or driving a car, you will be flying. Along the way you may visit a few cities and have a few layovers. Bad weather may even get in the way, but sooner or later you will get to your destination. Take a deep breath. Understand that the process will be one of learning, and that learning will be applicable in other aspects of your work. The result will be two-fold. First, a greater number of people will have access to your collections, and consequently, more people will be using your collections.
Projects

While the number of linked data websites is less than the worldwide total number, it is really not possible to list every linked data project but only things that will presently useful to the archivist and computer technologist working in cultural heritage institutions. And even then the list of sites will not be complete. Instead, listed below are a number of websites of interest today.

The list is divided into two parts: introductions, data sets and projects. The introductions are akin to directories or initial guilds filled with pointers to information about RDF especially meaningful to archivists (and other cultural heritage workers). The data sets and projects range from simple RDF dumps to full-blown discovery systems. In between some simple browsable lists and raw SPARQL endpoints.

Introductions

- **Datahub (http://datahub.io/) -** This is a directory of data sets. It includes descriptions of hundreds of data collections. Some of them are linked data sets. Some of them are not.

- **LODLAM (http://lodlam.net/) -** LODLAM is an acronym for Linked Open Data in Libraries Archives and Museums. LODLAM.net is a community, both virtual and real, of linked data aficionados in cultural heritage institutions. It, like OpenGLAM, is a good place to discuss linked data in general.

- **OpenGLAM http://openglam.org) -** GLAM is an acronym for Galleries, Libraries, Archives, and Museums. OpenGLAM is a community fostered by the Open Knowledge Foundation and a place to to discuss linked data that is "free". for It, like LODLAM, is a good place to discuss linked data in general.

- **semanticweb.org (http://semanticweb.org) -** semanticweb.org is a portal for publishing information on research and development related to the topics Semantic Web and Wikis.
Includes data.semanticweb.org and data.semanticweb.org/snorql.

Data sets and projects

• 20th Century Press Archives (http://zbw.eu/beta/p20) - This is an archive of digitized newspaper articles which is made accessible not only as HTML but a number of other metadata formats such as RDFa, METS/MODS and OAI-ORE. It is a good example of how metadata publishing can be mixed and matched in a single publishing system.

• AGRIS (http://agris.fao.org/openagris/) - Here you will find a very large collection of bibliographic information from the field of agriculture. It is accessible via quite a number of methods including linked data.

• D2R Server for the CIA Factbook (http://wifo5-03.informatik.uni-mannheim.de/factbook/) - The content of the World Fact Book distributed as linked data.

• D2R Server for the Gutenberg Project (http://wifo5-03.informatik.uni-mannheim.de/gutendata/) - This is a data set of Project Gutenburgh content -- a list of digitized public domain works, mostly books.

• Dbpedia (http://dbpedia.org/About) - In the simplest terms, this is the content of Wikipedia made accessible as RDF.

• FindAndConnect (http://www.findandconnect.gov.au) -

• LIBRIS (http://libris.kb.se) - This is the joint catalog of the Swedish academic and research libraries. Search results are presented in HTML, but the URLs pointing to individual items are really actionable URIs resolvable via content negotiation, thus support distribution of bibliographic information as RDF. This initiative is very similar to OpenCat.
• Linked Archives Hub Test Dataset (http://data.archiveshub.ac.uk) - This data set is RDF generated from a selection of archival finding aids harvested by the Archives Hub in the United Kingdom.

• Linked Movie Data Base (http://linkedmdb.org/) - A data set of movie information.

• Linked Open Data at Europeana (http://pro.europeana.eu/datasets) - A growing set of RDF generated from the descriptions of content in Europeana.

• Linking Lives (http://archiveshub.ac.uk/linkinglives/) - While this project has had no working interface, it is a good read on the challenges of presenting link data people (as opposed to computers). Its blog site enumerates and discusses issues from provenance to unique identifiers, from data clean up to interface design.

• LOCAH Project (http://archiveshub.ac.uk/locah/) - This is/ was a joint project between Mimas and UKOLN to make Archives Hub data available as structured Linked Data. (All three organizations are located in the United Kingdom.). EAD files were aggregated. Using XSLT, they were transformed into RDF/XML, and the RDF/XML was saved in a triple store. The triple store was then dumped as a file as well as made searchable via a SPARQL endpoint.

• OCLC Data Sets & Services (http://www.oclc.org/data/) - Here you will find a number of freely available bibliographic data sets and services. Some are available as RDF and linked data. Others are Web services.

• OpenCat (http://demo.cubicweb.org/opencatfresnes/) - This is a library catalog combining the authority data (available as RDF) provided by the National Library of France with works of a second library (Fresnes Public Library). Item level search results have URIs whose RDF is available via content negotiation. This project is similar to LIBRIS.
• PELAGIOS (http://pelagios-project.blogspot.com/p/about-pelagios.html) - A data set of ancient places.

• ReLoad (http://labs.regesta.com/progettoReload/en) - This is a collaboration between the Central State Archive of Italy, the Cultural Heritage Institute of Emilia Romagna Region, and Regesta.exe. It is the aggregation of EAD files from a number of archives which have been transformed into RDF and made available as linked data. Its purpose and intent are very similar to the purpose and intent of the combined LOCAH Project and Linking Lives.

• SNAC (http://socialarchive.iath.virginia.edu) -

• World Bank Linked Data (http://worldbank.270a.info/.html) - A data set of World Bank indicators, climate change information, finances, etc.
Tools and visualizations

This section lists various tools for archivists and computer technologists wanting to participate in various aspects of linked data. Here you will find pointers to creating, editing, storing, publishing, and searching linked data.

Directories

The sites listed in this section enumerate linked data and RDF tools. They are jumping off places to other sites:

- **ConverterToRdf** ([http://www.w3.org/wiki/ConverterToRdf](http://www.w3.org/wiki/ConverterToRdf)) - Hosted by the W3C this is a long list links pointing to applications that will convert various forms of data into RDF. The list is long, and defunct tools may not be updated as such.

- **Linked Data Tools** ([http://linkeddata.org/tools](http://linkeddata.org/tools)) - Linkeddata.org is the home of the famous linked data "cloud" image, and LinkedData.org also includes a number of directory-like pages on linked data in general. One of those pages is a list of linked data tools.

- **SemWebClients** ([http://www.w3.org/wiki/TaskForces/CommunityProjects/LinkingOpenData/SemWebClients](http://www.w3.org/wiki/TaskForces/CommunityProjects/LinkingOpenData/SemWebClients)) - Hosted by the W3C, this is a list of Semantic Web clients and applications.

- **RDFImportersAndAdapters** ([http://www.w3.org/wiki/RDFImportersAndAdapters](http://www.w3.org/wiki/RDFImportersAndAdapters)) - A list of tools and applications for converting various data and file formats into serialized RDF.

- **SIMILE RDFizers** ([http://simile.mit.edu/wiki/RDFizers](http://simile.mit.edu/wiki/RDFizers)) - Another list of tools for converting data and files into RDF.

- **SparqlImplementations** ([http://www.w3.org/wiki/SparqlImplementations](http://www.w3.org/wiki/SparqlImplementations)) - Another page hosted by the W3C,
and listing SPARQL clients and tools.

- **Tools** ([http://www.w3.org/2001/sw/wiki/Tools](http://www.w3.org/2001/sw/wiki/Tools)) - Hosted by the W3C, this page is a sort of directory of directories for all sort of linked data and RDF tools: editors, converters, SPARQL clients, triple stores, etc.

RDF converters, validators, etc.

- **ead2rdf** ([http://data.archiveshub.ac.uk/xslt/ead2rdf.xsl](http://data.archiveshub.ac.uk/xslt/ead2rdf.xsl)) - This is the XST stylesheet previously used by the Archives Hub in their LOCAH Linked Archives Hub project. It transforms EAD files into RDF/XML. A slightly modified version of this stylesheet was used to create the LiAM sandbox.

- **Protégé** ([http://protege.stanford.edu](http://protege.stanford.edu)) - Install this well-respected tool locally or use it as a hosted Web application to create OWL ontologies.

- **RAMP** ([http://www.rampeditor.info/](http://www.rampeditor.info/)) - "The Remixed Archival Metadata Project (RAMP) is a lightweight web-based editing tool that is intended to let users do two things: (1) generate enhanced authority records for creators of archival collections and (2) publish the content of those records as Wikipedia pages."

- **RDF2RDF** ([http://www.l3s.de/~minack/rdf2rdf/](http://www.l3s.de/~minack/rdf2rdf/)) - A handy Java jar file enabling you to convert various versions of serialized RDF into other versions of serialized RDF.

- **Vapour, a Linked Data Validator** ([http://validator.linkeddata.org/vapour](http://validator.linkeddata.org/vapour)) - Much like the W3C validator, this online tool will validate the RDF at the other end of a URI. Unlike the W3C validator, it echoes back and forth the results of the content negotiation process.

- **W3C RDF Validation Service** ([http://www.w3.org/RDF/Validator/](http://www.w3.org/RDF/Validator/)) - Enter a URI or paste an RDF/XML document into the text field, and a triple representation of the
corresponding data model as well as an optional graphical visualization of the data model will be displayed.

Linked data frameworks and publishing systems

- **4store** (http://4store.org/) - A linked data publishing framework for managing triple stores, querying them locally, querying them via SPARQL, dumping their contents to files, as well as providing support via a number of scripting languages (PHP, Ruby, Python, Java, etc.).

- **Apache Jena** (http://jena.apache.org/) - This is a set of tools for creating, maintaining, and publishing linked data complete a SPARQL engine, a flexible triple store application, and inference engine.

- **D2RQ** (http://d2rq.org/) - Use this application to provide a linked data front-end to any (well-designed) relational database. It supports SPARQL, content negotiation, and RDF dumps for direct HTTP access or uploading into triple store.

- **oai2lod** (https://github.com/behas/oai2lod) - This is a particular implementation D2RQ Server. More specifically, this tool is an intermediary between a OAI-PMH data providers and a linked data publishing system. Configure oai2lod to point to your OAI-PMH server and it will publish the server's metadata as linked data.

- **OpenLink Virtuoso Universal Server** (http://virtuoso.openlinksw.com) - This is a commercial version of OpenLink Virtuoso Open-Source Edition. It seems to be a platform for modeling and accessing data in a wide variety of forms: relational databases, RDF triples stores, etc. Again, feature-rich and well-documented.
openRDF Sesame (http://www.openrdf.org/) - This is a Java-based framework for implementing linked data publishing including the establishment of a triple store and a SPARQL endpoint.

OWLIM (https://www.ontotext.com/owlim) -

R2RML (http://www.w3.org/TR/r2rml/)

Semantic Web browsers

This is a small set of Semantic Web browsers. Give them URIs and they allow you to follow and describe the links they include.

Inspector (http://inspector.sindice.com) - Creates graphs, lists ontologies, generates a full-text report from literals, and lists triples found at the other end of URIs.

LinkSailor (http://linksailor.com) - Feed this interface a URI that points to many other actionable URIs, and it will return an interesting mash-up including images, paragraphs of texts, and hyperlinks to more content.

LOD Browser Switch (http://browse.semanticweb.org) - This is really a gateway to other Semantic Web browsers. Feed it a URI and it will create lists of URLs pointing to Semantic Web interfaces, but many of the URLs (Semantic Web interfaces) do not seem to work. Some of the resulting URLs point to RDF serialization converters.

LodLive (http://en.lodlive.it) - This Semantic Web browser allows you to feed it a URI and interactively follow the links associated with it. URIs can come from DBedia, Freebase, or one of your own.

Open Link Data Explorer (http://demo.openlinksw.com/rdfbrowser2/) - The most sophisticated Semantic Web browser in this set. Given a URI it creates various views of the resulting triples associated with including lists of all its properties and objects, networks graphs,
tabular views, and maps (if the data includes geographic points).

- Quick and Dirty RDF browser (http://graphite.ecs.soton.ac.uk/browser/) - Given the URL pointing to a file of RDF statements, this tool returns all the triples in the file and verbosely lists each of their predicate and object values. Quick and easy. This is a good for reading everything about a particular resource. The tool does not seem to support content negotiation.

If you need some URIs to begin with, then try some of these:

- Walt Disney via VIAF - http://viaf.org/viaf/36927108/

- origami via the Library of Congress - http://id.loc.gov/authorities/subjects/sh85095643

- Paris from DBpedia - http://dbpedia.org/resource/Paris
Ontologies & vocabularies

Directories of ontologies

- Linked Open Vocabularies (http://lov.okfn.org/dataset/lov/) - This is a list of more than 400 RDF ontologies with both a searchable/browsable interface. It is also accessible via linked data publishing principles.

- Open Metadata Registry (http://metadataregistry.net) - This is a list of more than 300 RDF ontologies. The Registry was originally conceived of as a National Science Foundation project called the National Science Foundation Digital Library (NSDL) Registry. The Registry seems heavy on sets of controlled vocabularies of a bibliographic nature.

Vocabularies

- Getty Vocabularies (http://vocab.getty.edu) - A set of thesauri used to "categorize, describe, and index cultural heritage objects and information".

- Library of Congress Linked Data Service (http://id.loc.gov/) - A set of data sets used for bibliographic classification: subjects, names, genres, formats, etc.

- VIAF (http://viaf.org/) - This data set functions as a name authority file. The human-readable interface is quite nice.

Ontologies

- Archival Collections Ontology (https://github.com/rubinsztajn/archival) - Created by Aaron Rubinstein (University of Massachusetts) is a small ontology.
specifically designed for archival collections.

- **Bibo** (http://purl.org/ontology/bibo/) - Just as the name infers, this ontology is intended to model bibliographic citations.

- **Bibframe** (http://bibframe.org) - Another ontology which is bibliographic in nature and includes an abundance of properties for various identifiers.

- **CIDOC Conceptual Reference Model** (http://www.cidoc-crm.org) - Intended for cultural heritage institutions, this model includes quite a number of subclass items surrounding two primary concepts: things and time.

- **Dublin Core Terms** (http://dublincore.org/documents/dcmi-terms/) - This ontology is rather bibliographic in nature, and provides a framework for describing many of archival descriptions.

- **Europeneana** (http://ontogenealogy.com/europeana-data-model-edm/) - Another approach is to the data model from other organizations. Since Europeneana’s data is intended to be available as linked data, then it might be a good model to explore – http://pro.europeana.eu/edm-documentation Specifically: For the archival community, collection level descriptions such as EAD play a major role. They fit neatly under the EDM, in particular the notion of ore:aggregation allows for describing archival “fonds”. The International Council of Archives just started the discussion about a common conceptual model similar to FRBR or the CRM. In the meanwhile, with the CRM historical facts associated with archival contents can be described in more detail than just on the EDM level (Stasinopoulou et. al. 2007). Further, collection-level descriptions in Dublin Core are quite convenient and becoming popular for archival descriptions. –

- **FOAF** (http://www.foaf-project.org/) - Friend Of A Friend (FOAF) is a popular and often-quoted ontology for modeling people and the social networks they create: names, email
address, social network account identifiers, etc.

- **LOCAH RDF Vocabulary** ([http://data.archiveshub.ac.uk/def/](http://data.archiveshub.ac.uk/def/)) - This is the model designed for the LOCAH Project from the Archives Hub in the United Kingdom. It is the model underpinning the transformed EAD files of the LiAM "sandbox".

- **MARC21 Vocabularies from Metadata Management Associates** ([http://marc21rdf.info](http://marc21rdf.info)) -

- **OAD Vocabulary** - ([http://labs.regesta.com/progettoReload/wp-content/uploads/2013/08/oadNew.html](http://labs.regesta.com/progettoReload/wp-content/uploads/2013/08/oadNew.html)) - "[Google translation] The definition of an ontology of archival description is needed in order to test the potential of the web of data to archival descriptions. The archival description aims at the representation of a unit of description by collecting, analyzing, organizing and recording the information needed to identify, manage, locate and explain the context and documentary material and the storage systems that produced (ISAD (G)). The ontology of archival description (SRO) has as its goal the formal representation of the descriptions of the individual units of description - understood as objects of their archival descriptions. In particular, the SRO waiver to take into account all the individual elements of these descriptions, in endless variations they present as part of the archival systems in which they are hinged, but instead seeks only to explain the elements of information deemed necessary for the exposure the web of data units of archival description to ensure integration with other datasets published also in format Linked Open Data. SROs, in beta, is expressed in OWL (Ontology Web Language): it takes into account all the elements of archival description in the standard ISAD (G): general international standard archival description, adopted by the ICA (International Council on Archives) integrating them with other information elements not covered by the standard mentioned - as the index entries - and with links to creators and conservative. The formal mechanisms provided by the standard RDF and OWL have made it possible to bring the information elements of archival descriptions
expressed in an ontology SROs to "external" concepts representative of traditional archival descriptive and based on the international standard ISAD (G). Since the experiments conducted by the partners of the project ReLoad had as object data encoded on the basis of the framework EAD (Encoded Archival Description), the ontology provides for a specific class OAD "eadElement" designed to encode the information on the element or attribute of the EAD scheme used by the organization that provides data archival description, which is also attributed to the ISAD (G) on the basis of official mapping ISAD (G) - EAD

- OWL (http://www.w3.org/2001/sw/wiki/OWL) -

- PROV (http://www.w3.org/TR/prov-overview/) - for provenance information.

- RDF - This ontology is necessary because linked data is manifested as... RDF

- RDFS (http://www.w3.org/TR/rdf-schema/) - This ontology may be necessary because the archival community may be creating some of its own ontologies.

- Schema.org (http://schema.org) - Originally sponsored by Google, Microsoft, Yahoo, etc. this ontology is advocated by the major Internet search engines. It is a growing, well-supported ontology, and it is seemingly designed for just about anything under the sun.

- SKOS (http://www.w3.org/2004/02/skos/) - This ontology is used to create thesauri.

- VoID (http://semanticweb.org/wiki/VoID) - This relatively simple data model is used to describe RDF data sets with things like their location, size, licensing terms, frequency of updates, etc.
Content-negotiation and cURL

This is the tiniest of introductions to content negotiation and cURL.

The computer technology behind linked data is about two things: 1) serializing RDF, and 2) making it available on the Web. Various RDF serializations are described in another section of the Guidebook. The second thing, making RDF available on the Web, can be accomplished in any number of ways, including but not necessarily limited to: 1) embedded in HTML as RDFa, 2) "dumps" of RDF, 3) SPARQL interfaces, and 3) content negotiation. Exploiting RDFa was discussed in a previous section. A number of the data sets in Projects section make their RDF available as "dumps". The next section of the Guidebook is a tutorial on SPARQL. This section describes content negotiation and a command line tool called cURL, which is very helpful for understanding content negotiation.

Content negotiation is an HTTP-pure technique for exchanging data on the Web. In the briefest of descriptions, content negotiation is a client-server technique where the client application first requests some data via a URI in a specific format (plain text, HTML, PDF, RDF/XML, etc.). The server responses with either a "file not found" error, or a URL where the request can be satisfied. It is then up to the client to make a second request with the given URL to obtain the desired data. Content negotiation and the complementary "REST-ful" computing are the primary means of Web-based data exchange, and it is interesting to note the differences between the two. Content negotiation only requires an (in-depth) knowledge of HTTP to implement. Given a URI and a thorough knowledge of HTTP, a programmer can effectively harvest linked data. On the other hand, REST-ful interfaces, while requiring less knowledge of HTTP, are often specific to individual websites. They also often require API "keys" as well as the use of very long URLs complete with domain-specific name/value pairs. Content negotiation is more standards-based when compared to REST-ful computing, but REST-ful computing is easier to initially grasp. Both have their advantages and disadvantages, but content negotiation is the way of linked data.

CURL is a command-line tool making it easier for you to see the Web as data and not presentation. Consequently it is a very good tool for learning about content negotiation. Please don't be afraid of cURL because it is a command-line utility. Understanding how to use cURL
and to do content-negotiation by hand will take you a long way in understanding linked data.

The first step is to download and install cURL. If you have a Macintosh or a Linux computer, then it is probably already installed. If not, then give the cURL download wizard a whirl. We'll wait.

Next, you need to open a terminal. On Macintosh computers a terminal application is located in the Utilities folder of your Applications folder. It is called "Terminal". People using Windows-based computers can find the "Command" application by searching for it in the Start Menu. Once cURL has been installed and a terminal has been opened, then you can type the following command at the prompt to display a help text:

```
curl --help
```

There are many options there, almost too many. It is often useful to view only one page of text at a time, and you can "pipe" the output through to a program called "more" to do this:

```
curl --help | more
```

By pressing the space bar, you can go forward in the display. By pressing "b" you can go backwards, and by pressing "q" you can quit.

Feed cURL the complete URL of Google's home page to see how much content actually goes into their "simple" presentation:

```
curl http://www.google.com/ | more
```

The communication of the World Wide Web (the hypertext transfer protocol or HTTP) is divided into two parts: 1) a header, and 2) a body. By default cURL displays the body content. To see the header, add the -I (for a mnemonic, think "information") to the command:

```
curl -I http://www.google.com/
```

The result will be a list of characteristics the remote Web server is using to describe this particular interaction between itself and cURL.

---

43 cURL download wizard - [http://curl.haxx.se/dlwiz/](http://curl.haxx.se/dlwiz/)
The most important things to note are: 1) the status line and 2) the content type. The status line will be the first line in the result, and it will say something like "HTTP/1.1 200 OK", meaning there were no errors. Another line will begin with "Content-Type:" and denotes the format of the data being transferred. In most cases the content type line will include something like "text/html" meaning the content being sent is in the form of an HTML document.

Now feed cURL a URI for Walt Disney, such as one from DBpedia:

```bash
curl http://dbpedia.org/resource/Walt_Disney
```

The result will be empty, but upon the use of the -I switch you can see how the status line changed to "HTTP/1.1 303 See Other". This means there is no content at the given URI, and the line starting with "Location:" is a pointer — an instruction — to go to a different document. In the parlance of HTTP this is called redirection. Using cURL going to the recommended location results in a stream of HTML:

```bash
curl http://dbpedia.org/page/Walt_Disney | more
```

Most Web browsers automatically follow HTTP redirection commands, but cURL needs to be told this explicitly through the use of the -L switch. (Think "location"). Consequently, given the original URI, the following command will display HTML even though the URI has no content:

```bash
curl -L http://dbpedia.org/resource/Walt_Disney | more
```

Now remember, the Semantic Web and linked data depend on the exchange of RDF, and upon closer examination you can see there are "link" elements in the resulting HTML, and these elements point to URLs with the .rdf extension. Feed these URLs to cURL to see an RDF representation of the Walt Disney data:

```bash
curl http://dbpedia.org/data/Walt_Disney.rdf | more
```

Downloading entire HTML streams, parsing them for link elements containing URLs of RDF, and then requesting the RDF is not nearly as efficient as requesting RDF from the remote server in the first place. This can be done by telling the remote server you accept RDF as a format type. This is accomplished through the use of the -H switch.
(Think "header"). For example, feed cURL the URI for Walt Disney and specify your desire for RDF/XML:

```
```

Ironically, the result will be empty, and upon examination of the HTTP headers (remember the -I switch) you can see that the RDF is located at a different URL, namely, http://dbpedia.org/data/Walt_Disney.xml:

```
```

Finally, using the -L switch, you can use the URI for Walt Disney to request the RDF directly:

```
```

That is cURL and content-negotiation in a nutshell. A user-agent submits a URI to a remote HTTP server and specifies the type of content it desires. The HTTP server responds with URLs denoting the location of the desired content. The user-agent then makes a more specific request. It is sort of like the movie. "One URI to rule them all." In summary, remember:

- cURL is a command-line user-agent
- given a URL, cURL returns, by default, the body of an HTTP transaction
- the -I switch allows you to see the HTTP header
- the -L switch makes cURL automatically follow HTTP redirection requests
- the -H switch allows you to specify the type of content you wish to accept
- given a URI and the use of the -L and -H switches you are able to retrieve either HTML or RDF
Use cURL to actually see linked data in action, and here are a few more URIs to explore:

- Walt Disney via VIAF - http://viaf.org/viaf/36927108/
- origami via the Library of Congress - http://id.loc.gov/authorities/subjects/sh85095643
- Paris from DBpedia - http://dbpedia.org/resource/Paris
This is the simplest of SPARQL tutorials. The tutorial's purpose is two-fold: 1) through a set of examples, introduce the reader to the syntax of SPARQL queries, and 2) to enable the reader to initially explore any RDF triple store which is exposed as a SPARQL endpoint.

SPARQL (SPARQL protocol and RDF query language) is a set of commands used to search RDF triple stores. It is modeled after SQL (structured query language), the set of commands used to search relational databases. If you are familiar with SQL, then SPARQL will be familiar. If not, then think of SPARQL queries as formalized sentences used to ask a question and get back a list of answers.

Also, remember, RDF is a data structure of triples: 1) subjects, 2) predicates, and 3) objects. The subjects of the triples are always URIs -- identifiers of "things". Predicates are also URIs, but these URIs are intended to denote relationships between subjects and objects. Objects are preferably URIs but they can also be literals (words or numbers). Finally, RDF objects and predicates are defined in human-created ontologies as a set of classes and properties where classes are abstract concepts and properties are characteristics of the concepts.

Try the following steps with just about any SPARQL endpoint:

1. Get an overview - A good way to begin is to get a list of all the ontological classes in the triple store. In essence, the query below says, "Find all the unique objects (classes) in the triple store where any subject is a type of object, and sort the result by object."

   SELECT DISTINCT ?o WHERE { ?s a ?o } ORDER BY ?o

2. Learn about the employed ontologies - Ideally, each of the items in the result will be an actionable URI in the form of a "cool URL". Using your Web browser, you ought to be able to go to the URL and read a thorough description of the given class, but the URLs are not always actionable.

3. Learn more about the employed ontologies - Using the following query you can create a list of all the properties in the triple store as well as infer some of the characteristics of each class.
Unfortunately, this particular query is intense. It may require a long time to process or may not return at all. In English, the query says, "Find all the unique predicates where the RDF triple has any subject, any predicate, or any object, and sort the result by predicate."

```
```

4. Guess - Steps #2 and Step #3 are time intensive, and consequently it is sometimes easier just browse the triple store by selecting one of the "cool URLs" returned in Step #1. Submit a modified version of Step #1's query. It says, "Find all the subjects where any RDF subject (URI) is a type of object (class)". Using the LiAM triple store, the following query tries to find all the things that are EAD finding aids.

```
SELECT ?s WHERE { ?s a <http://data.archiveshub.ac.uk/def/FindingAid> }
```

5. Learn about a specific thing - The result of Step #4 ought to be a list of (hopefully actionable) URIs. You can learn everything about that URI with the following query. It says, "Find all the predicates and objects in the triple store where the RDF triple's subject is a given value and the predicate and object are of any value, and sort the result by predicate". In this case, the given value is one of the items returned from Step #4.

```
```

6. Repeat a few times - If the results from Step #5 returned seemingly meaningful and complete information about your selected URI, then repeat Step #5 a few times to get a better feel for some of the "things" in the triple store. If the results were not meaningful, then got to Step #4 to browser another class.

7. Take these hints - The first of these following two queries generates a list of ten URIs pointing to things that came from MARC records. The second query is used to return everything about a specific URI whose data came from a MARC record.

```
SELECT ?s WHERE { ?s a <http://simile.mit.edu/2006/01/ontologies/mods3#Record> } LIMIT 10
```
8. Read the manual - At this point, it is a good idea to go back to Step #2 and read the more formal descriptions of the underlying ontologies.

9. Browse some more - If the results of Step #3 returned successfully, then browse the objects in the triple store by selecting a predicate of interest. The following queries demonstrate how to list things like titles, creators, names, and notes.

```
SELECT ?s ?o WHERE { ?s <http://simile.mit.edu/2006/01/roles#creator> ?o } ORDER BY ?o LIMIT 100
SELECT ?s ?o WHERE { ?s <http://xmlns.com/foaf/0.1/name> ?o } ORDER BY ?o LIMIT 100
SELECT ?s ?o WHERE { ?s <http://data.archiveshub.ac.uk/def/note> ?o } ORDER BY ?o LIMIT 100
```

10. Read about SPARQL - This was the tiniest of SPARQL tutorials. Using the LiAM data set as an example, it demonstrated how to do the all but simplest queries against an RDF triple store. There is a whole lot more to SPARQL than SELECT, DISTINCT, WHERE, ORDER BY, and LIMIT commands. SPARQL supports a short-hand way of denoting classes and properties called PREFIX. It supports Boolean operations, limiting results based on "regular expressions", and a few mathematical functions. SPARQL can also be used to do inserts and deletes against triple stores. The next step is to read more about SPARQL. Consider reading the canonical documentation from the W3C, "SPARQL by example", and the Jena project's "SPARQL Tutorial".  

Finally, don't be too intimidated about SPARQL. Yes, it is possible to submit SPARQL queries by hand, but in reality, person-friendly front-ends are expected to be created making search much easier.

44 canonical documentation - [http://www.w3.org/TR/rdf-sparql-query/](http://www.w3.org/TR/rdf-sparql-query/)

45 SPARQL By Example - [https://www.cambridgeanalytics.com/semantic-university/sparql-by-example](https://www.cambridgeanalytics.com/semantic-university/sparql-by-example)

46 SPARQL Tutorial - [http://jena.apache.org/tutorials/sparql.html](http://jena.apache.org/tutorials/sparql.html)
Glossary

• API - (see application programmer interface)

• application programmer interface (API) - an abstracted set of functions and commands used to get output from remote computer applications. These functions and commands are not necessarily tied to any specific programming language and therefore allow programmers to use a programming language of their choice.

• cool URL - a relatively short, human-readable pointer to Internet accessible content. Cool URLs are expected to be constant, in that they don't change. Additionally and in general, cool URLs do not include question marks (?) nor name/value pairs denoting queries.

• content negotiation - a process whereby a user-agent and HTTP server mutually decide what data format will be exchanged during an HTTP request. In the world of linked data, content negotiation is very important when URIs are requested because content negotiation helps determine whether or not HTML or serialized RDF will be returned.

• extensible markup language (XML) - a standardized data structure made up of a minimum of rules and can be easily used to represent everything from tiny bits of data to long narrative texts. XML is designed to be read by people as well as computers, but because of this it is often considered verbose, and ironically, difficult to read.

• file transfer protocol (FTP) - A Internet standard for copying files from one Internet host to another.

• FTP - (see file transfer protocol)

• HTML - (see hypertext markup language)

• HTTP - (see hypertext transfer protocol)

• hypertext markup language (HTML) - an XML-like data structure intended to be rendered by user-agents whose
output is for people to read. For the most part, HTML is used to markup text and denote a text's stylistic characteristics such as headers, paragraphs, and list items. It is also used to markup the hypertext links (URLs) between documents.

• hypertext transfer protocol (HTTP) - the formal name for the way the World Wide Web operates. It begins with one computer program (a user-agent) requesting content from another computer program (a server) and getting back a response. Once received, the response is formatted for reading or for processing by a computer program. The shape and content of both the request and the response are what make-up the protocol.

• Javascript object notation (JSON) - like XML, a data structure allowing arbitrarily large sets of values to be associated with an arbitrarily large set of names (variables). JSON was first natively implemented as a part of the Javascript computer language, but has since become popular in other computer languages as well.

• JSON - (see Javascript object notation)

• linked data - the content and technical process for making real the ideas behind the Semantic Web. It begins with the creation of serialized RDF and making the serialization available via HTTP. User agents are then expected to harvest the RDF, combine it with other harvested RDF, and ideally use it to bring to light new or existing relationships between real world objects -- people, places, and things -- thus creating and enhancing human knowledge.

• linked open data - a qualification of linked data whereby the information being exchanged is expected to be "free" as in gratis.

• OAI - (see Open Archives Initiative-Protocol for Metadata Harvesting)
• ontology - a highly structured vocabulary, and in the parlance of linked data, used to denote, describe, relate, and qualify the predicates of RDF triples. Ontologies have been defined for a very wide range of human domains, everything from bibliography (Dublin Core or MODS), to people (FOAF), to sounds (Audio Features).

• Open Archives Initiative-Protocol for Metadata Harvesting (OAI-PMH) - a metadata publishing standard consisting of a set commands whereby information is listed, requested, and exchanged between two computers in the Internet. OAI-PMH is complementary to the principles and practices of linked data.

• RDF - (see resource description framework)

• representational state transfer (REST) - a process for querying remote HTTP servers and getting back computer-readable results. The process usually employs denoting name-value pairs in a URL and getting back something like XML or JSON.

• resource description framework - the conceptual model for describing the knowledge of the Semantic Web. It is rooted in the notion of triples whose subjects and objects are literally linked with other triples through the use of URIs.

• REST - (see representational state transfer)

• Semantic Web - an idea articulated by Tim Berners Lee whereby human knowledge is expressed in a computer-readable fashion and made available via HTTP so computers can harvest it and bring to light new information or knowledge.

• serialization - a manifestation of RDF; one of any number of textual expressions of RDF triples. Examples include but are not limited to RDF/XML, RDFa, N3, and JSON-LD.

• SPARQL - (see SPARQL protocol and RDF query language)
• SPARQL protocol and RDF query language (SPARQL) - a formal specification for querying and returning results from RDF triple stores. It looks and operates very much like the structured query language (SQL) of relational databases complete with its SELECT, WHERE, and ORDER BY clauses.

• triple - the atomistic facts making up RDF. Each fact is akin to a rudimentary sentence with three parts: 1) subject, 2) predicate, and 3) object. Subjects are expected to be URIs. Ideally, objects are URIs as well, but can also be literals (words, phrases, or numbers). Predicates are akin to the verbs in a sentence and they denote a relationship between the subject and object. Predicates are expected to be a member of a formalized ontology.

• triple store - a database of RDF triples usually accessible via SPARQL

• universal resource identifier (URI) - a unique pointer to a real-world object or a description of an object. In the parlance of linked data, URIs are expected to have the same shape and function as URLs, and if they do, then the URIs are often described as "actionable".

• universal resource locator (URL) - an address denoting the location of something on the Internet. These addresses usually specify a protocol (like http), a host (or computer) where the protocol is implemented, and a path (directory and file) specifying where on the computer the item of interest resides.

• URI - (see universal resource identifier)

• URL - (see universal resource locator)

• user agent - this is the formal name for what is commonly called a "Web browser", but Web browsers usually denote applications where people are viewing the results. User agents are usually "Web browsers" whose readers are computer programs.
XML - (see extensible markup language)

For a more complete and exhaustive glossary, see the W3C's Linked Data Glossary.47

This is a list of links and citations to get one started on Linked Open Data

Summers, Ed, and Dorothea Salo. Linking Things on the Web: A Pragmatic Examination of Linked Data for Libraries, Archives and Museums. ArXiv

Scripts

This section lists a set of computer source code implementing a simple linked data publishing system. Assuming the (Perl) developer has on hand a set of EAD finding aids and/or sets of MARC records, this system can:

- transform EAD into RDF/XML
- transform EAD into HTML
- convert MARC into RDF/XML
- convert MARC into HTML
- support content negotiation against the RDF/XML and HTML
- initialize a triple store
- batch load RDF/XML into the triple store
- search the triple store
- dump the entire triple store as RDF/XML
- support a SPARQL endpoint against the triple store

This publishing system is more than a toy and ought to be able to support the needs of many archives with small- to medium-sized collections.

    return <<EOF
<html>
<head>
<title>LiAM SPARQL Endpoint</title>
</head>
<body style='margin: 7%'>
<h1>LiAM SPARQL Endpoint</h1>

EOF
}
This is a brain-dead and half-baked SPARQL endpoint to a subset of LiAM linked data. Enter a query, but there is the disclaimer. Errors will probably happen because of SPARQL syntax errors. Remember, the interface is brain-dead. Your milage will vary.

```html
<form method='GET' action='./'>
<textarea style='font-size: large' rows='5' cols='65' name='query' />
SELECT ?p ?o
ORDER BY ?p
</textarea><br />
<input type='submit' value='Search' />
</form>
```

Sample queries:

- **All the classes in the triple store**
  ```sparql
  SELECT DISTINCT ?o WHERE { ?s a ?o } ORDER BY ?o
  ```

- **All the properties in the triple store**
  ```sparql
  ```

- **All the things that are archival finding aids**
  ```sparql
  SELECT ?s WHERE { ?s &lt;http://data.archiveshub.ac.uk/def/FindingAid&gt; }
  ```

- **Everything about a specific actionable URI (finding aid)**
  ```sparql
  ```

- **Ten things that are MARC records**
  ```sparql
  SELECT ?o WHERE { ?s &lt;http://purl.org/dc/terms/title&gt; ?o } ORDER BY ?o LIMIT 100
  ```

- **One hundred things with creators**
  ```sparql
  SELECT ?o WHERE { ?s &lt;http://purl.org/dc/terms/creator&gt; ?o } ORDER BY ?o LIMIT 100
  ```

- **One hundred things with names**
  ```sparql
  SELECT ?o WHERE { ?s &lt;http://xmlns.com/foaf/0.1/name&gt; ?o } ORDER BY ?o LIMIT 100
  ```

- **One hundred things with notes**
  ```sparql
  SELECT ?o WHERE { ?s &lt;http://data.archiveshub.ac.uk/def/note&gt; ?o } ORDER BY ?o LIMIT 100
  ```

For more information about SPARQL, see:
SPARQL Query Language for RDF from the W3C

Source code -- sparql.pl -- is available online.

Question from a library school student

In January of 2014 I received the following email message from a library school student. The questions they asked were apropos to the Guide, so I thought I’d include my response here, but the names have been changed to protect the innocent.

From: Eric Lease Morgan <emorgan@nd.edu>
Subject: Re: RDF ontologies discussion on Code4Lib Listserv
Date: January 21, 2014 at 9:36:36 PM EST

> I'm writing you to ask you about your thoughts on implementing these kinds of RDF descriptions for institutional collections. Have you worked on a project that incorporated LD technologies like these descriptions? What was that experience like? Also, what kind of strategies have you used to implement these strategies, for instance, was considerable buy-in from your organization necessary, or were you able to spearhead it relatively solo? In essence, what would it "cost" to really do this?
>
> I apologize for the mass of questions, especially over e-mail. My only experience with ontology work has been theoretical, and I haven't met any professionals in the field yet who have actually used it. When I talk to my mentors about it, they are aware of it from an academic standpoint but are wary of it due these questions of cost and resource allocation, or confusion that it doesn't provide anything new for users. My final project was to build an ontology to describe some sort of resource and I settled on building a vocabulary to describe digital facsimiles and their physical artifacts, but I have yet to actually implement or use any of it. Nor have I had a chance yet to really use any preexisting vocabularies. So I've found myself in a slightly frustrating position where I've studied this from an academic perspective and seek to incorporate it in my GLAM work, but I lack the hands-on opportunity to play around with it.
>
> --
> MLIS Candidate

Dear MLS Candidate, no problem, really, but I don’t know how much help I will really be.
The whole RDF / Semantic Web thing started more than ten years ago. The idea was to expose RDF/XML, allow robots to crawl these files, amass the data, and discover new knowledge – relationships – underneath. Many in the library profession thought this was science fiction and/or the sure pathway to professional obsolescence. Needless to say, it didn’t get very far. A few years ago the idea of linked data was articulated, and it a nutshell it outlined how to make various flavors of serialized RDF available via an HTTP technique called content negotiation. This was when things like Turtle, N3, the idea of triple stores, maybe SPARQL, and other things came to fruition. This time the idea of linked data was more real and got a bit more traction, but it is still not main stream.

I have very little experience putting the idea of RDF and linked data into practice. A long time ago I created RDF versions of my Alex Catalogue and implemented a content negotiation tool against it. The Catalogue was not a part of any institution other than myself. When I saw the call for the LiAM Guidebook I applied and got the “job” because of my Alex Catalogue experiences as well as some experience with a thing colloquially called The Catholic Portal which contains content from EAD files.

I knew this previously, but linked data is all about URIs and ontologies. Minting URIs is not difficult, but instead of rolling your own, it is better to use the URIs of others, such as the URIs in DBpedia, GeoNames, VIAF, etc. The ontologies used to create relationships between the URIs are difficult to identify, articulate, and/or use consistently. They are manifestations of human language, and human language is ambiguous. Trying to implement the nuances of human language in computer “sentences” called RDF triples is only an approximation at best. I sometimes wonder if the whole thing can really come to fruition. I look at OAI-PMH. It had the same goals, but it was finally called not a success because it was too difficult to implement. The Semantic Web may follow suit.

That said, it is not too difficult to make the metadata of just about any library or archive available as linked data. The technology is inexpensive and already there. The implementation will not necessarily implement best practices, but it will not expose incorrect nor invalid data, just data that is not the best. Assuming the library has MARC or EAD files, it is possible to use XSL to transform the metadata into
RDF/XML. HTML and RDF/XML versions of the metadata can then be saved on an HTTP file system and disseminated either to humans or robots through content negotiation. Once a library or archive gets this far they can then either improve their MARC or EAD files to include more URIs, they can improve their XSLT to take better advantage of shared ontologies, and/or they can dump MARC and EAD all together and learn to expose linked data directly from (relational) databases. It is an iterative process which is never completed.

Nothing new to users? Ah, that is the rub and a sticking point with the linked data / Semantic Web thing. It is a sort of chicken & egg problem. “Show me the cool application that can be created if I expose my metadata as linked data”, say some people. On the other hand, “I can not create the cool application until there is a critical mass of available content.” Despite this issue, things are happening for readers, namely mash-ups. (I don’t like the word “users”.) Do a search in Facebook for the Athens. You will get a cool looking Web page describing Athens, who has been there, etc. This was created by assembling metadata from a host of different places (all puns intended), and one of those places were linked data repositories. Do a search in Google for the same thing. Instead of just bringing back a list of links, Google presents you with real content, again, amassed through various APIs including linked data. Visit VIAF and search for a well-known author. Navigate the result an you will maybe end up at WorldCat identities where all sorts of interesting information about an author, who they wrote with, what they wrote, and where is displayed. All of this is rooted in linked data and Web Services computing techniques. This is where the benefit comes. Library and archival metadata will become part of these mash-up – called “named graphs” – driving readers to library and archival websites. Linked data can become part of Wikipedia. It can be used to enrich descriptions of people in authority lists, gazetteers, etc.

What is the cost? Good question. Time is the biggest expense. If a person knows what they are doing, then a robust set of linked data could be exposed in less than a month, but in order to get that far many people need to contribute. Systems types to get the data out of content management systems as well as set up HTTP servers. Programmers will be needed to do the transformations. Catalogers will be needed to assist in the interpretation of AACR2 cataloging practices, etc. It will take a village to do the work, and that doesn’t even count convincing people this is a good idea.
Your frustration is not uncommon. Often times if there is not a real world problem to solve, learning anything new when it comes to computers is difficult. I took BASIC computer programming three times before anything sunk in, and it only sunk in when I needed to calculate how much money I was earning as a taxi driver.

Try implementing one of your passions. Do you collect anything? Baseball cards? Flowers? Books? Records? Music? Art? Is there something in your employer’s special collections of interest to you? Find something of interest to you. For simplicity’s sake, use a database to describe each item in the collection making sure each record in our database includes a unique key field. Identify one or more ontologies (others as well as rolling your own) whose properties match closely the names of your fields in your database. Write a program against your database to create static HTML pages. Put the pages on the Web. Write a program against your database to create static RDF/XML (or some other RDF serialization). Put the pages on the Web. Implement a content negotiation script that takes the keys to your database’s fields as input and redirects HTTP user agents to either the HTML or RDF. Submit the root of your linked data implementation to Datahub.io. Ta da! You have successfully implemented linked data and learned a whole lot along the way. Once you get that far you can take what you have learned and apply it in a bigger and better way for a larger set of data.

On one hand the process is not difficult. It is a matter of repurposing the already existing skills of people who work in cultural heritage institutions. On the other hand, change in the ways things are done is difficult (but not as difficult in the what of what is done). The change is difficult to balance existing priorities.

Exposing library and archival content as linked data represents a different working style, but the end result is the same – making the content of our collections available for use and understanding.

HTH.

About the author

Eric Lease Morgan is a Digital Initiatives Librarian at the University of Notre Dame. He considers himself to be a librarian first and a computer user second. His professional goal is to discover new ways to use computers to provide better library services. An advocate of open source software and open access publishing, he has been freely giving this intellectual property away since before the phrases were coined. This Guidebook is the fourth book-length thing he has written. Others included: 1) WAIS and Gopher Servers: A Guide for Internet End-Users, 2) Pointers 4 Searching, Searching 4 Pointers, and 3) Open Source Software in Libraries. He has written and presented consistently throughout his career, and just about all of his writings can be found online at one of two places:

1. Musings on Information and Librarianship (http://infomotions.com/musings/) - pretty much all of Eric's published work from the beginning of his career until 2010

2. Planet Eric Lease Morgan (http://planet.infomotions.com) - an aggregation of all his postings from as many as five different blogs

Eric also exhibits his paints, plays guitar, grows roses, likes to row in his boat, and binds his own handmade books.
